Stochastic chemical reactions

The SSA algorithm (and other equivalent methods) computes each reaction one by one – exact but very costly

"Tau-leaping" is equivalent to the Euler-Maruyama method for SDEs – the rates λ_k are frozen at the start of the timestep, so for each timestep of size h just need a sample from a Poisson distribution $Poiss(\lambda_k h)$ to obtain the number of reactions in that timestep.

i.e. for piecewise constant $\lambda(s)$,

$$Y\left(\int_{0}^{(n+1)h}\lambda(s) \mathrm{d}s
ight) - Y\left(\int_{0}^{nh}\lambda(s) \mathrm{d}s
ight) \sim \textit{Poiss}(\lambda h)$$

Anderson & Higham (2012) developed (and analysed) a very elegant and efficient multilevel version of this algorithm – big savings because finest level usually has 1000's of timesteps.

Key challenge: how to couple coarse and fine path simulations?

Crucial observation: for $t_1, t_2 \ge 0$

$$Poiss(t_1) + Poiss(t_2) \stackrel{d}{=} Poiss(t_1+t_2)$$

Stochastic chemical reactions

Solution (for uniform timesteps with refinement factor of 2)

- simulate the Poisson variable on the coarse timestep as the sum of two fine timestep Poisson variables
- couple the fine path and coarse path Poisson variables by using common variable based on smaller of two rates

If $\lambda_n^f < \lambda_n^c$, use $Poiss(\lambda_n^c h) \sim Poiss(\lambda_n^f h) + Poiss((\lambda_n^c - \lambda_n^f) h)$ If $\lambda_n^c < \lambda_n^f$, use $Poiss(\lambda_n^f h) \sim Poiss(\lambda_n^c h) + Poiss((\lambda_n^f - \lambda_n^c) h)$

Tau-leaping MLMC algorithm

Input: fine timestep *h*, final time T = N h, refinement factor *M*, initial states $\hat{X}^f = \hat{X}^c = X$

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

for
$$n = 1, N$$
 do
for each k do
compute λ_k^f , and also λ_k^c if $mod(n-1, M) = 0$
 $R_{1,k} := Poiss(min(\lambda_k^f, \lambda_k^c)h)$
 $R_{2,k} := Poiss(|\lambda_k^f - \lambda_k^c|h)$
 $\widehat{X}^f := \widehat{X}^f + (R_{1,k} + 1_{\lambda_k^c > \lambda_k^c} R_{2,k}) \zeta_K$
 $\widehat{X}^c := \widehat{X}^c + (R_{1,k} + 1_{\lambda_k^c > \lambda_k^f} R_{2,k}) \zeta_K$
end for
end for

Anderson & Higham also analysed the variance and proved that

$$\mathbb{E}[\|\widehat{X}^f - \widehat{X}^c\|^2] = O(h).$$

Since the cost is $O(h^{-1})$ this is very similar to the Euler-Maruyama method applied to SDEs, and the overall complexity is $O(\varepsilon^{-2}|\log \varepsilon|^2)$ for ε RMS error (independent of the total number of reactions performed).

The Anderson/Higham coupling is very elegant and effective, but not the only possibility

The key thing is to

▶ make sure the telescoping sum is respected so you are estimating the same $\mathbb{E}[P_{\ell}]$ in both $\mathbb{E}[P_{\ell+1}-P_{\ell}]$ and $\mathbb{E}[P_{\ell}-P_{\ell-1}]$

• try to minimise the variance $\mathbb{V}[P_{\ell} - P_{\ell-1}]$

Alternative couplings: I

Go back to original formulation of tau-leaping

$$\widehat{X}(t_n) = \widehat{X}(0) + \sum_k R_k(t_n) \zeta_k$$

where

$$R_k(t) = Y_k\left(\int_0^t \lambda_k(\widehat{X}(s)) \,\mathrm{d}s\right)$$

and

$$\widehat{X}(s)=\widehat{X}(t_m), ext{ for } s\in [t_m,t_{m+1}),$$

and use the same underlying unit-rate Poisson process Y_k for both fine and coarse paths.

▲□▶▲□▶▲≡▶▲≡▶ ≡ めぬる

Alternative couplings: I

The implementation might be quite tricky – I don't think anyone has tried this.

Might require "Binomial bridge" conditional sampling: given $Y(t_1)$ and $Y(t_2)$, then for any $t_1 < t < t_2$ we know that

$$Y(t) - Y(t_1) \sim B(Y(t_2) - Y(t_1), (t-t_1)/(t_2-t_1))$$

where B(n,p) returns value k with probability $\binom{n}{k} p^k (1-p)^k$

Alternative couplings: II

For a scalar random variable X with a cumulative ditribution function (CDF)

$$C(x) = \mathbb{P}(X < x)$$

can generate samples X using $X = C^{-1}(U)$ where U is a uniform random variable on (0, 1).

For the coupling, we need two Poisson variates $Poiss(\lambda_1 h)$ and $Poiss(\lambda_2 h)$ for the same fine timestep. Hence, use the same U, and invert slightly different Poisson CDF's to obtain the random variables.

Alternative couplings: II

Input: fine timestep *h*, final time T = N h, initial states $\hat{X}^f = \hat{X}^c = X$ for n = 1, N do for each *k* do

compute λ_k^f , and also λ_k^c if mod(n-1, M) = 0generate uniform r.v. U $R_k^f := C_{Poiss}^{-1}(\lambda_k^f h, U)$ $R_k^c := C_{Poiss}^{-1}(\lambda_k^c h, U)$ $\widehat{\chi}^f := \widehat{\chi}^f + R_k^f \zeta_K$ $\widehat{\chi}^c := \widehat{\chi}^c + R_k^c \zeta_K$ end for

end for

MLMC

Previously, I have said that the usual MLMC estimator is

$$Y_\ell = \widehat{P}_\ell(\omega) - \widehat{P}_{\ell-1}(\omega)$$

for the same $\omega \in \Omega$.

That works in many situations, but sometimes (as in this case) it is not clear what it means to have the same ω for both \hat{P}_{ℓ} and $\hat{P}_{\ell-1}$.

What we really need is

$$\blacktriangleright \mathbb{E}[Y_{\ell}] = \mathbb{E}[\widehat{P}_{\ell}] - \mathbb{E}[\widehat{P}_{\ell-1}]$$

$$\blacktriangleright \ \mathbb{V}[Y_{\ell}] \ll 1$$

MLMC

So a more general definition is

$$\widehat{Y}_\ell = \widehat{P}_\ell(\mu) - \widehat{P}_{\ell-1}(
u)$$

where the joint distribution (μ, ν) has the correct marginals for μ and ν .

This links to the Wasserstein metric measuring the distance between two probability measures μ, ν :

$$W_{\rho}(\mu,\nu) \equiv (\inf \mathbb{E}[d(X,Y)^{\rho}])^{1/\rho}$$

where the inf is over all couplings such that X and Y have marginals μ and ν respectively. In 1D, an optimal coupling is given by

$$X = C_{\mu}^{-1}(U), Y = C_{\nu}^{-1}(U),$$

where $U \sim U(0,1)$ is a unit interval uniform r.v.

Extra bits

Once the timestep is reduced down to a size for which there are very few reactions per timestep, it makes sense to switch to SSA.

Anderson & Higham (2012) came up with a very nice way to couple the finest tau-leaping level to an SSA treatment, so the final algorithm is unbiased.

The key idea is the "coarse" path uses tau-leaping, and the "fine" path uses the exact updating of the rates λ , and each reaction k can be split it into two reactions:

- one with rate $\min(\lambda^f, \lambda^c)$
- one with rate $|\lambda^f \lambda^c|$

then use either Direct Method or Next Reaction Method for coupled simulation.

This leads to an $O(\varepsilon^{-2})$ complexity overall, with only a $(\log N)^2$ dependence on the number of reactions per path.

Extra bits

Model reduction: some biochemical reaction networks are very complex – can use a simpler approximate model (e.g. based on some forward-backward reactions being in equilibrium) as an additional "level"

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

Anderson & Higham (2012) also give an example of this.

Extra bits - adaptation

Adaptive time-stepping:

- Can be helpful to improve accuracy, especially when there is a fast initial transient.
- MLMC treatment essentially the same as for SDEs.

Adaptive treatment of reactions:

some handled by SSA, some by tau-leaping, perhaps even some as Langevin SDEs

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

▶ This has been explored by Moraes *et al* (2016)

Extra bits – level 0 c.v.

Moraes *et al* (2016) also introduced an interesting control variate for the very coarsest tau-leaping level.

Start from

$$X(t) = X(0) + \sum_{k} Y_k \left(\int_0^t \lambda_k(X(s)) \, \mathrm{d}s
ight) \zeta_k,$$

replace Y_k by identity, since $\mathbb{E}[Y_k(s)] = s$, to get

$$Z(t) = X(0) + \sum_{k} \left(\int_{0}^{t} \lambda_{k}(Z(s)) \, \mathrm{d}s \right) \, \zeta_{k}, \quad \Longrightarrow \dot{Z} = \sum_{k} \lambda_{k} \, \zeta_{k}$$

and then we have the approximation

$$\widetilde{X}(t) = X(0) + \sum_{k} Y_k \left(\int_0^t \lambda_k(Z(s)) \, \mathrm{d}s \right) \, \zeta_k.$$

Extra bits – level 0 c.v.

Defining

$$K = \int_0^T \lambda_k(Z(s)) \, \mathrm{d}s$$

then

$$\mathbb{E}[\widetilde{X}(T)] = X(0) + \sum_{k} K \zeta_{k}$$

and for any polynomial f(X) can compute $\mathbb{E}[f(\widetilde{X}(T))]$.

 $\widetilde{X}(T)$ can then be simulated using the same Y_k as the coarsest level tau-leaping \widehat{X} simulation.

Probably good opportunities for further research in this area

Maybe explore applications in stochastic event simulation for Operational Research?

Also interesting challenges in writing generic high performance software
