## Stochastic Simulation: Lecture 14

#### Prof. Mike Giles

Oxford University Mathematical Institute

(ロ)、(型)、(E)、(E)、(E)、(O)へ(C)

In Practical 3, you will be working with a software which implements the multilevel Monte Carlo method:

▶ mlmc.m / mlmc.py / mlmc.cpp: "driver" code which performs the MLMC calculation using a user routine to estimate E[P<sub>ℓ</sub> − P<sub>ℓ−1</sub>] using N<sub>ℓ</sub> samples

mlmc\_test.m / mlmc\_test.py / mlmc\_test.cpp: routine which does a lot of tests and then calls mlmc to perform a number of MLMC calculations

### Details of MLMC code

mlmc\_test first performs a set of calculations using a fixed number of samples on each level of resolution, and produces 4 plots:

▶ 
$$\log_2(V_\ell)$$
 versus level  $\ell$ 

If  $V_\ell \sim 2^{-\beta \ell}$  then the slope of this line should asymptote towards  $-\beta$ 

▶ 
$$\log_2(|\mathbb{E}[P_{\ell} - P_{\ell-1}]|)$$
 versus level  $\ell$ 

If  $|\mathbb{E}[P_{\ell} - P_{\ell-1}]| \sim 2^{-\alpha\ell}$  then the slope of this line should asymptote towards  $-\alpha$

- consistency check versus level
- kurtosis versus level

#### Consistency check

If a, b, c are estimates for  $\mathbb{E}[P_{\ell-1}]$ ,  $\mathbb{E}[P_{\ell}]$ ,  $\mathbb{E}[P_{\ell} - P_{\ell-1}]$ , then it should be true that  $a - b + c \approx 0$ .

The consistency check verifies that this is true, to within the accuracy one would expect due to sampling error.

Since

$$\sqrt{\mathbb{V}[\mathbf{a} - \mathbf{b} + \mathbf{c}]} \leq \sqrt{\mathbb{V}[\mathbf{a}]} + \sqrt{\mathbb{V}[\mathbf{b}]} + \sqrt{\mathbb{V}[\mathbf{c}]}$$

it computes the ratio

$$\frac{|\mathbf{a} - \mathbf{b} + \mathbf{c}|}{3(\sqrt{\mathbb{V}[\mathbf{a}]} + \sqrt{\mathbb{V}[\mathbf{b}]} + \sqrt{\mathbb{V}[\mathbf{c}]})}$$

The probability of this ratio being greater than 1 based on random sampling errors is extremely small. If it is, it indicates a likely programming error.

### Kurtosis check

The MLMC approach needs a good estimate for  $V_{\ell} = \mathbb{V}[P_{\ell} - P_{\ell-1}]$ , but how many samples are need for this?

As few as 10 may be sufficient in many cases for a rough estimate, but many more are needed when there are rare outliers.

When the number of samples N is large, the standard deviation of the sample variance for a random variable X with zero mean is approximately

$$\sqrt{rac{\kappa-1}{N}} \, \mathbb{E}[X^2]$$
 where kurtosis  $\kappa$  is defined as  $\kappa = rac{\mathbb{E}[X^4]}{(\mathbb{E}[X^2])^2}$ 

(http://mathworld.wolfram.com/SampleVarianceDistribution.html)

As well as computing  $\kappa_{\ell}$ , mlmc\_test will give a warning if  $\kappa_{\ell}$  is very large.

## Kurtosis check

An extreme (but important) example is a digital option in which P always takes the value 0 or 1.

In this case we have

$$X \equiv P_{\ell} - P_{\ell-1} = \left\{egin{array}{cc} 1, & ext{probability } p \ -1, & ext{probability } q \ 0, & ext{probability } 1 - p - q \end{array}
ight.$$

If  $p,q\ll 1$ , then  $\mathbb{E}[X]pprox 0$ , and

$$\kappapproxrac{p+q}{(p+q)^2}=(p+q)^{-1}\gg 1$$

Therefore, many samples are required for a good estimate of  $V_{\ell}$ , and if we don't have many samples, we may even get all  $X^{(n)} = 0$ , which will give an estimated variance of zero.

# MLMC algorithm

```
start with L\!=\!2, and initial target of N_0 samples on levels \ell=0,1,2
```

```
while extra samples need to be evaluated do
  evaluate extra samples on each level
  compute/update estimates for V_{\ell}, C_{\ell}, \ell = 0, \ldots, L
  define optimal N_{\ell}, \ \ell = 0, \dots, L
  if no new samples needed then
    test for weak convergence
    if not converged then
       if L == L_{max} then
         print warning message - failed to converge
       else
         set L := L+1, and initialise target N_l
       end if
    end if
  end if
end while
```

### MLMC algorithm

Objective: to achieve

$$\mathsf{MSE} = \sum_{\ell=0}^{L} V_{\ell} / N_{\ell} + \left( \mathbb{E}[P_{L} - P] \right)^{2} \leq \varepsilon^{2}$$

by choosing L such that

$$\left(\mathbb{E}[P_L - P]\right)^2 \le \theta \,\varepsilon^2$$

and  $N_\ell$  such that

$$\sum_{\ell=0}^{L} V_{\ell}/N_{\ell} \leq (1\!-\!\theta) \, \varepsilon^2$$

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三三 - のへぐ

I used to use  $\theta = 0.5$ , but now tend to use  $\theta = 0.25$ .

#### MLMC – optimal $N_{\ell}$

Given L, optimal choice for  $N_\ell$  is

$$N_{\ell} = \frac{1}{1-\theta} \varepsilon^{-2} \sqrt{V_{\ell}/C_{\ell}} \sum_{\ell'=0}^{L} \left( \sqrt{V_{\ell'} C_{\ell'}} \right)$$

 $V_{\ell}$  is estimated from empirical variance.

In python code,  $C_{\ell} = 2^{\gamma \ell}$ , where  $\gamma$  is user input.

In MATLAB and C++ code user defines  $C_{\ell}$ , for example by counting how many random numbers are generated.

#### MLMC – convergence check

If  $\mathbb{E}[P_\ell\!-\!P_{\ell-1}]\,\propto\,2^{-lpha\ell}$  then the remaining error is

$$\mathbb{E}[P-P_L] = \sum_{\ell=L+1}^{\infty} \mathbb{E}[P_\ell - P_{\ell-1}] \approx \mathbb{E}[P_L - P_{L-1}] \sum_{k=1}^{\infty} 2^{-\alpha k}$$
$$= \mathbb{E}[P_L - P_{L-1}] / (2^{\alpha} - 1)$$

We want  $|\mathbb{E}[P - P_L]| < \sqrt{\theta} \ \varepsilon$ , so that gives the convergence test

$$|\mathbb{E}[P_L - P_{L-1}]| \ / \ (2^{lpha} - 1) < \sqrt{ heta} \ arepsilon$$

For robustness, we extend this check to extrapolate also from the previous two data points  $\mathbb{E}[P_{L-1}-P_{L-2}]$ ,  $\mathbb{E}[P_{L-2}-P_{L-3}]$ , and take the maximum over all three as the estimated remaining error.

```
% function [P, N1, cost] = mlmc(mlmc_1,N0,eps,Lmin,Lmax,
