

- ⑤ Try to eliminate  $m_0$  and  $\lambda_0$  in favor of  $m$  and  $\lambda$  in all physical quantities
- ⑥ If the resulting expressions have a finite limit as the regulator is removed, e.g.  $\Lambda \rightarrow \infty$  or  $D \rightarrow 4$ , the theory is renormalizable  $\rightarrow$  we can express all measurable observables in terms of a set of others.

### Renormalization of $\phi^4$

① Relabeling:

$$S = \int \left( \frac{1}{2} (\partial \phi_0)^2 + \frac{1}{2} m_0^2 \phi_0^2 + \frac{\lambda_0}{4!} \phi_0^4 \right) d^D x$$

and

$$G_0^{(N)}(y_1, \dots, y_N) = \langle \phi_0(y_1) \dots \phi_0(y_N) \rangle$$

② What is the origin of divergencies?

Short answer: Loop integrals

Parts which are tree-like are problem-free

Example:

If both parts are finite then also their product is finite  $\rightarrow$  the original diagram is finite

- We need to focus only on diagrams which cannot be divided into two disjoint parts with a one line cut  $\rightarrow$  1PI diagrams  
 $\uparrow$   
 one-particle-irreducible

- External propagators are always finite  
 $\rightarrow$  we can truncate them

- At the end we study

$$\Gamma_0^{(N)}(p_1, \dots, p_N) = \prod_{j=1}^N \tilde{G}_0^{(2)}(p_j)^{-1} \tilde{G}_0^{(N)}(p_1, \dots, p_N) \Big|_{1PI}$$

$\uparrow$   
vertex functions

Example:

$$\Gamma_0^{(2)}(p) = \tilde{G}_0^{(2)}(p)^{-1}$$

### Counting divergences

- Any diagram depends on a number of loop momenta  $(k_1, \dots, k_l)$ , where  $l$  is the number of loops.

- UV divergences come from the region where some of  $k_j$ 's are large  $\rightarrow$  focus on the region where

$$k_j \sim K \rightarrow \text{large } \forall j$$

For  $l$ -loop diagram with  $P$  propagators, the divergence

is:

$$\delta = l \cdot D - 2P \quad (\text{superficial degree of divergence})$$

# Divergences

If  $\delta \geq 0$  - diagram primitively divergent

If  $\delta < 0$  - not clear: there still can be divergences coming from regions where some  $k_i$ 's are large while others are not

## More refined analysis (diagram independent)

Calculate mass dimensions:

$$[\rho] = 1, [x] = -1, [S] = 0$$

$$\Rightarrow [\phi] = \frac{D-2}{2} \text{ and } [\lambda_0] = 4-D$$

Correlators in position space:

$$[G_0^{(N)}] = \frac{N(D-2)}{2}$$

In momentum space:

$$[\tilde{G}_0^{(N)}] = \underbrace{D}_{\substack{\uparrow \\ \text{delta} \\ \text{function}}} - N \cdot \underbrace{D}_{\substack{\uparrow \\ \text{integrations}}} + N \frac{D-2}{2}$$

and

$$[\Gamma_0^{(N)}] = N + D - N \frac{D}{2}$$

When expanded in powers of  $\lambda_0$ :

$$\Gamma_0^{(N)} = \sum_{n=0}^{\infty} \Gamma_{0,n}^{(N)} \lambda_0^n$$

← given by a sum of 1PI Feynman diagrams

Divergence of  $\Gamma_{0,n}^{(N)}$ :

$$\delta = D + N \left(1 - \frac{D}{2}\right) + n(D-4)$$

If  $\delta \geq 0 \rightarrow$  primitively divergent

We distinguish three cases:

-  $D < 4$  :  $[\Gamma_{0,n}^{(2)}] = 2 + n(D-4)$  and  $[\Gamma_n^{(N)}] < 0$  for  $N > 2$

→ only a finite number of diagrams is divergent, namely, ones contributing to  $\Gamma_n^{(2)}$  up to the order  $n \leq \frac{2}{4-D}$

-  $D = 4$  :  $[\Gamma_0^{(2)}] = 2$ ,  $[\Gamma_0^{(4)}] = 0$  are primitively divergent to all orders.

Critical dimension of the theory (coupling dimensionless)

-  $D > 4$  : all  $\Gamma_0^{(N)}$  are primitively divergent if evaluated to sufficiently high-order (non-renormalizability)

Comment: The critical dimension and the number of primitively divergent  $\Gamma_0^{(N)}$  at the critical dimension depend on a theory.

• What about other divergences (not primitive)

Example:

← not divergent for  $D=4$  but contains a divergent subgraph

- this kind of divergences occur in subdiagrams at lower order in  $\lambda_0$  than the whole diagram

- we implement the renormalization procedure order-by-order: these divergences are already dealt with.

③ Regularization: every regulator introduces a mass scale

• cut-off  $\Lambda \rightarrow [\Lambda] = 1$

• dimensional regularization:  $D = 4 - 2\epsilon$ ,  $\epsilon > 0$  small

$$[\lambda_0] = 2\epsilon$$

Introduce a dimensionless coupling constant

$$g_0 = \mu^{-2\epsilon} \lambda_0$$

↑                    ↑                    ↑  
[g<sub>0</sub>] = 0            [μ] = 1            [λ<sub>0</sub>] = 2ε

④ Mass renormalization

• We have already evaluated  $\tilde{G}_0^{(2)}$  to one-loop

$$\tilde{G}_0^{(2)}(p) = \frac{1}{p^2 + m_0^2} + \frac{-\lambda_0}{2} \frac{1}{(p^2 + m_0^2)^2} I_2 + \mathcal{O}(\lambda_0^2)$$

with  $I_2 = \frac{\pi^{D/2}}{(2\pi)^D} \Gamma(1 - \frac{D}{2}) m_0^{D-2}$

• Then the two-point vertex function:

$$\Gamma_0^{(2)}(p) = \tilde{G}_0^{(2)}(p)^{-1} = p^2 + m_0^2 + \frac{\lambda_0}{2} I_2 + \mathcal{O}(\lambda_0^2)$$

The position of the pole of  $\tilde{G}_0^{(2)}$ , or the zero of  $\Gamma_0^{(2)}$ , do not occur at  $p^2 = -m_0^2$ , but rather depends on  $\lambda_0$ .

We can define renormalized mass ~~as~~  $m^2$  as

$$\Gamma_0^{(2)}(p^2 = -m^2) = 0$$

Since  $I_2$  is independent of  $p$ :

$$m^2 = m_0^2 + \frac{\lambda_0}{2} I_2 + \mathcal{O}(\lambda_0^2)$$

- Note that  $m^2 > m_0^2$  so in the massless limit ( $m^2 \rightarrow 0$ )  $m_0^2$  is negative  $\rightarrow$  it underlines the fact that  $m_0$  is not a physical parameter.
- For higher orders  $\Gamma_{0,n}^{(2)}(p)$  depends on  $p$  and then  $m$  is given only implicitly.

## Field renormalization

- Assume  $D=4 \rightarrow \Gamma_0^{(2)}(p)$  diverges quadratically.

One can expand it around  $p^2 = -m^2$

$$\Gamma_0^{(2)}(p) = \underbrace{\Gamma_0^{(2)}(p^2 = -m^2)}_{\parallel 0} + \underbrace{(p^2 + m^2) \frac{\partial \Gamma_0^{(2)}(p)}{\partial p^2} \Big|_{p^2 = -m^2}}_{\text{divergent, with the degree } \delta = 0 \rightarrow \text{logarithmic divergence}}$$

- How can we absorb this divergence?

$\rightarrow \Gamma_0^{(2)}$  is defined ~~as~~ using  $\langle \phi_0 \phi_0 \rangle$  but  $\phi_0$  is just an integration variable and it has no physical meaning.

Define a physical field:

$$\phi(x) = Z_p^{-1/2} \phi_0(x)$$

$\longleftarrow$  field renormalization constant

Then

$$G^{(n)}(y_1, \dots, y_n) \equiv \langle \phi(y_1) \dots \phi(y_n) \rangle = Z_p^{-n/2} \langle \phi_0(y_1) \dots \phi_0(y_n) \rangle$$

This implies:

$$\Gamma^{(N)} = Z_\phi^{N/2} \Gamma_0^{(N)}$$

•  $Z_\phi$  is fixed by the requirement

$$\left. \frac{\partial \Gamma^{(2)}(p)}{\partial p^2} \right|_{p^2 = -m^2} = 1$$

or equivalently

$$Z_\phi^{-1} = \left. \frac{\partial \Gamma_0^{(2)}(p)}{\partial p^2} \right|_{p^2 = -m^2}$$

### Coupling constant renormalization

Assume  $D=4$ .  $\Gamma_0^{(4)}$  is primitively divergent to all orders. We define renormalized coupling constant

$$-\lambda \equiv \Gamma^{(4)} \left( \underset{\substack{\uparrow \\ \vec{p} = \vec{0}}}{(m, \vec{0})}, (m, \vec{0}), (-m, \vec{0}), (-m, \vec{0}) \right)$$

This interaction can be measured in experiments and fixes  $\lambda$ .
