Generative deep nets (Goodfellow et al. 14')

Generative model from 100 latent variables

Train the two network parameters using the objective $\min_{G} \max_{D} n^{-1} \sum_{\mu=1}^{n} \log(D(x_{\mu}, y_{\mu})) + p^{-1} \sum_{p} \log(1 - D(G(z_{p}), y_{p}))$

Algorithm 1 Minibatch stochastic gradient descent training of generative adversarial nets. The number of steps to apply to the discriminator, k, is a hyperparameter. We used k = 1, the least expensive option, in our experiments.

for number of training iterations do

for k steps do

- Sample minibatch of m noise samples $\{z^{(1)}, \ldots, z^{(m)}\}$ from noise prior $p_g(z)$.
- Sample minibatch of m examples $\{x^{(1)}, \ldots, x^{(m)}\}$ from data generating distribution $p_{\text{data}}(x)$.
- Update the discriminator by ascending its stochastic gradient:

$$abla_{ heta_d} rac{1}{m} \sum_{i=1}^m \left[\log D\left(oldsymbol{x}^{(i)}
ight) + \log \left(1 - D\left(G\left(oldsymbol{z}^{(i)}
ight)
ight)
ight)
ight].$$

end for

- Sample minibatch of m noise samples $\{z^{(1)}, \ldots, z^{(m)}\}$ from noise prior $p_g(z)$.
- Update the generator by descending its stochastic gradient:

$$abla_{\theta_g} rac{1}{m} \sum_{i=1}^m \log\left(1 - D\left(G\left(\boldsymbol{z}^{(i)}\right)\right)\right).$$

end for

The gradient-based updates can use any standard gradient-based learning rule. We used momentum in our experiments.

Generative deep nets (Radford et al. 16')

Early training examples

Figure 2: Generated bedrooms after one training pass through the dataset. Theoretically, the model could learn to memorize training examples, but this is experimentally unlikely as we train with a small learning rate and minibatch SGD. We are aware of no prior empirical evidence demonstrating memorization with SGD and a small learning rate.

https://arxiv.org/pdf/1511.06434.pdf

Wasserstein GAN (Arjovsky et al. 17')

Optimal transport decoder

One of the central challenges with GANs is the ability to train the parameters. Improvements have been made through choice of generative architecture (DC-GAN of Radford) and through different training objective functions (W-GAN)

Algorithm 1 WGAN with gradient penalty. We use default values of $\lambda = 10$, $n_{\text{critic}} = 5$, $\alpha = 0.0001$, $\beta_1 = 0$, $\beta_2 = 0.9$.

Require: The gradient penalty coefficient λ , the number of critic iterations per generator iteration n_{critic} , the batch size m, Adam hyperparameters α, β_1, β_2 .

Require: initial critic parameters w_0 , initial generator parameters θ_0 .

1: while θ has not converged do

```
2:
              for t = 1, \dots, n_{\text{critic}} do
 3:
                     for i = 1, ..., m do
 4:
                            Sample real data x \sim \mathbb{P}_r, latent variable z \sim p(z), a random number \epsilon \sim U[0, 1].
 5:
                            \tilde{x} \leftarrow G_{\theta}(z)
                            \hat{x} \leftarrow \epsilon \hat{x} + (1 - \epsilon) \tilde{x}
 6:
                            L^{(i)} \leftarrow D_w(\tilde{\boldsymbol{x}}) - D_w(\boldsymbol{x}) + \lambda(\|\nabla_{\tilde{\boldsymbol{x}}} D_w(\hat{\boldsymbol{x}})\|_2 - 1)^2
 7:
                     end for
 8.
                     w \leftarrow \operatorname{Adam}(\nabla_w \frac{1}{m} \sum_{i=1}^m L^{(i)}, w, \alpha, \beta_1, \beta_2)
 9:
10:
              end for
              Sample a batch of latent variables \{z^{(i)}\}_{i=1}^m \sim p(z).
11:
              \theta \leftarrow \operatorname{Adam}(\nabla_{\theta} \frac{1}{m} \sum_{i=1}^{m} -D_{w}(G_{\theta}(z)), \theta, \alpha, \beta_{1}, \beta_{2})
12:
13. end while

э

Large scale WGAN (Karras et al. 18')

Growing the encoder/decoder complexity

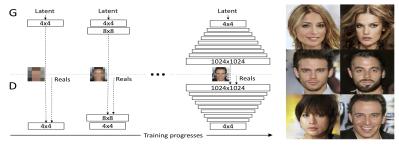

Figure 1: Our training starts with both the generator (G) and discriminator (D) having a low spatial resolution of 4×4 pixels. As the training advances, we incrementally add layers to G and D, thus increasing the spatial resolution of the generated images. All existing layers remain trainable throughout the process. Here $\boxed{N \times N}$ refers to convolutional layers operating on $N \times N$ spatial resolution. This allows stable synthesis in high resolutions and also speeds up training considerably. One the right we show six example images generated using progressive growing at 1024×1024 .

Understanding individual units in a DNN (Bau et al. 20')

OXFORD Institute

Single units which reliably detect object classes

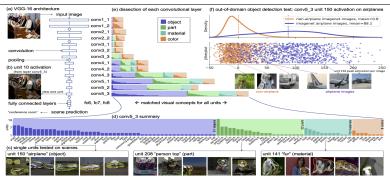

Fig. 1. The emergence of single-unit object detectors within a VGG-16 scene classifier. (a) VGG-16 consists of 13 convolutional layers, cov1_1 through coxt=3, ollowed by three fully connected layers, ccf.7, (b. (b) The activation of a single filter on a input image can be visualized as the region where the filter activates beyond its top 1% quantified level. (c) Single units are scored by matching high-activating regions against as et of human-interpretable visual concepts, each unit is labeled with its best-matching concept and visualized with maximally-activating images. (c) Concepts that matching in convolutional layer are summarized, showing a broad diversity of detectors to objects, object parts, materials, and colors. Many concepts are associated with multiple units. (e) Comparing all the layers of the network reveals that most object detectors earroge at the last convolutional layers. (f) Although the training set of challes, unit 15 de metals, unit 15 de metals, with a training and concepts activations to the unit on randomity are appled 1.00 arriginate and 1.000 non-airplane objects, as tested against a dataset of labeled object images not previously see by the network. The jitter jot shows peak activations for the unit on randomity are appled 1.00 arriginate and 1.000 non-airplane langes, and the urves show the kernel density estimates of these activations of the set of these activations.

(日)

Understanding individual units in a DNN (Bau et al. 20')

OXFORD Institute

Single units which reliably generate object classes

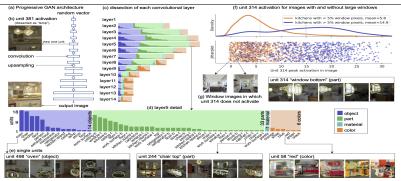

Fig. 3. The emergence of object: and part-specific units within a Progressive GAN generator(19), (a) The analyzed Progressive GAN consists of 15 convolutional layers that transform a random input vector into a synthesized image of a kitchen. (b) A single filter is visualized as the region of the output image where the filter activates beyond its top 1% quantile level; note that the filters are all precursors to the output. (c) Dissecting all the layers of the network shows a peak in object-specific units at 1_ayers 6 of the network (c) A detailed examination of 1_ayers shows more part-specific units than objects, and many visual concepts to responding to multiple units. (c) Units do not correspond to exact pixel patterns: a wide range of visual appearances for overs and chairs are generated when an oven or chair part unit are activated. (g) When a unit specific to window parts is tested as a classifier, on avonge the unit accivates more strongly on generated images that contain. larges that contain larges that contain larges that do not. (g) Some counterexamples: images for any chair on stronges to a classifier, on avonge the unit activates more stronge on to activate but where windows are synthesized nevertheles.

* □ > < □ > < □ > < □ > < □ >

Editing individual units in a DNN (Bau et al. 20')

Removing units of classes decreases their generation

(c) Effect of activating "door" units depends on location

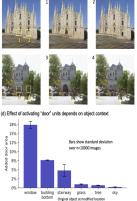

Fig. 4. The causal effect of altering units within a GAN generator. (a) When successively larger sets of units are removed from a GAN trained to generate outdoor church scenes, the tree area of the generated images is reduced. Removing 20 tree units removes more than half the generated tree pixels from the output. (b) Qualitative results: removing tree units affects trees while leaving other objects intact. Building parts that were previously occluded by trees are rendered as if revealing the objects that were behind the trees. (c) Doors can be added to buildings by activating 20 door units. The location, shape, size, and style of the rendered door depends on the location of the activated units. The same activation levels produce different doors. or no door at all (case 4) depending on locations. (d) Similar context dependence can be seen quantitatively: doors can be added in reasonable locations such as at the location of a window, but not in abnormal locations such as on a tree or in the sky.

Provable defense: convex polytope pt. 1 (Wong et al. 17)

Ensuring neighbourhood also classified correctly

Possible output of net $f_{\theta}(\cdot)$ from bounded perturbation is a non-convex set, say $\mathcal{Z}_{\epsilon}(x) = \{f_{\theta}(x + \delta) : \|\delta\|_{\infty} \leq \epsilon\}$. A convex outer-polytope of $\mathcal{Z}_{\epsilon}(x)$, say $\mathcal{Z}_{\epsilon}^{conv}(x)$, can be computed by replacing the input to each activation with a 2D convex set:

Figure 1. Conceptual illustration of the (non-convex) adversarial polytope, and an outer convex bound.

Requires knowledge of lower and upper bound for each input to a nonlinear activation. Let $c = e_{\ell} - e_{\ell'}$ or $c = 2e_{\ell} - 1_{|class|}$ and solve:

min $c^T \hat{z}_{\ell}$ and if nonnegative then robust to ϵ perturbation. $\hat{z}_{\ell} \in \hat{z}_{\epsilon}(x)$

Robustness via sparsification (Gopalakrishnan et al. 18)

Removing small values improves Lipshitz constant

Sparse network

(日)

Figure 1: Sparsifying front end defense: For a basis in which the input is sparse, the input is projected onto the subspace spanned by the K largest basis coefficients. This attemates the impact of the attack by K/N, where N is the input dimension.

Figure 2: Network sparsity defense: Imposing sparsity *within* the neural network attenuates the worst-case growth of the attack as it flows up the network.

Theorem 2. Consider an ℓ_{∞} -constrained input perturbation $e_0 = e$, with $||e||_{\infty} \leq \epsilon$. Suppose that we impose ℓ_1 constraints on the weights at each layer as follows:

$$\left\|\boldsymbol{w}_{ij}\right\|_{1} \leq \gamma_{j} \ \forall \ i$$

Then the effect of the perturbation is ℓ_{∞} -bounded at each layer:

$$\left\|\boldsymbol{e}_{j}\right\|_{\infty} \leq \epsilon \prod_{l=1}^{j} \gamma_{l} \tag{2}$$

Robustness via sparsification (Gopalakrishnan et al. 18)

More gradual decrease in accuracy as perturbation energy increases
