# THE GÖDEL INCOMPLETENESS THEOREMS 

R. W. Knight<br>Hilary 2023

#### Abstract

ABOUT THE LECTURE NOTES This document was originally written as a script for a live event (the lectures), which would be fleshed out with ad libs, comments from the audience, etc.

Even though real lectures are happening (as they weren't during lockdown), the videos that were made (in a hurry, like many things in $2020 / 2021$ ) are still available. The videos are not a read-through of the notes, nor are they a video version of the lectures. The videos concentrate on the parts that I think are most difficult, passing over some of the easier stuff. The tone of the videos is also less formal than that of the notes, and they concentrate on trying to get over the intuitions and some of the motivation. Also, the videos will be on the wrong side of any subsequent edits to these notes.

I hope to edit these lecture notes from time to time. I'm unlikely, unfortunately, to have enough time to edit the videos. If anything is unclear, or confusing, please email me, and I will respond as quickly as I can (though that may not be very).

Latest edit: 3rd May 2024.

Everything in the lectures or on the problem sheets is on the syllabus and examinable, unless otherwise indicated.*

Prerequisites: an introductory course in logic is assumed.

[^0]
## 0. Introduction

We will usually assume that the semiring ( $\mathbb{N}, 0,1,+, \cdot$ ) exists and has the usual familiar properties (from which it will follow that various axiom systems for it are consistent, since they have a model).

I assume familiarity with the Completeness Theorem of first-order logic; so when I prove a statement such as $S \vdash \phi$ ( $\phi$ is formally provable from assumptions $S$ ) I will on the whole not provide a formal proof of $\phi$ from $S$; I will instead argue that such a formal proof exists (which is quite different and much easier). I also assume some skill in distinguishing language from metalanguage and theorems from metatheorems.

These lectures are based on lecture notes by Dan Isaacson, and on Raymond Smullyan's book Gödel's Incompleteness Theorems (OUP, 1992). However, I sometimes depart (in notation or in other respects) from both sources.

## 1. A formal language for arithmetic

### 1.1. The language itself

We choose a formal language to make Gödel numbering more straightforward.
Definition 1.1.1. The symbols of the language $\mathscr{L}_{E}$ are:

$$
\overline{0}^{+} v f^{\prime}() \neg \rightarrow \forall=\leq \#
$$

An expression in $\mathscr{L}_{E}$ is any finite, non-empty sequence of symbols of $\mathscr{L}$ that does not begin with ${ }^{+}$.

The rules of syntax are as follows.
Definition 1.1.2. The terms of $\mathscr{L}_{E}$ are defined as follows.
$\overline{0}$ is a numeral term, and if $\sigma$ is a numeral term, then so is $\sigma^{+}$. We will write $\overline{0}$ followed by $n^{+}$'s as $\bar{n}$.
$v$ is $a$ variable term, and if $\tau$ is a variable term, then so is $\tau^{\prime}$. If $n$ is a natural number (including zero), then we'll write $v_{n}$ for $v$ followed by $n$ 's.

The function labels are $f, f^{\prime}$, and $f^{\prime \prime}$.
$A$ term is a numeral term, a variable term, an expression $\sigma^{+}$where $\sigma$ is a term, or an expression $(\tau \sigma v)$, where $\sigma$ is a function label and $\tau$ and $v$ are terms.
Definition 1.1.3. $\mathscr{L}_{E}$ contains the following formulae.
An atomic formula is an expression $\sigma=\tau$ or $\sigma \leq \tau$, where $\sigma$ and $\tau$ are terms.
Other formulae are: $\neg \phi,(\phi \rightarrow \psi), \forall x \phi$, where $\phi$ and $\psi$ are formulae, and $x$ is a variable term.

We sometimes write $(\phi \vee \psi)$ for $(\neg \phi \rightarrow \psi),(\phi \wedge \psi)$ for $\neg(\neg \phi \vee \neg \psi)$, $(\phi \leftrightarrow \psi)$ for $((\phi \rightarrow \psi) \wedge(\psi \rightarrow \phi))$, and $\exists x \phi$ for $\neg \forall v_{i} \neg \phi$, where $\phi$ and $\psi$ are formulae, and $v_{i}$ is a variable term.
Definition 1.1.4. If $x$ and $y$ are finite sequences of symbols in $\mathscr{L}_{E}$, then their concatenation $x \frown y$ is the sequence obtained by adding $y$ after $x$.
Definition 1.1.5. $\mathscr{L}$ is the sublanguage of $\mathscr{L}_{E}$ containing no occurrences of $f^{\prime \prime}$.

### 1.2. Logical rules

Given the Completeness Theorem of first-order Predicate Calculus, it does not much matter which system of axioms and logical rules we use. We choose to use one which makes it easier to prove the (meta)theorems we want to use (but which is also difficult to use for constructing formal proofs).

So, we use the following axiom schemes:
Definition 1.2.1. The logical axioms are all instances of the following schemata, where $\phi, \chi$ and $\psi$ may be any formulae:
(A1) $(\phi \rightarrow(\chi \rightarrow \phi))$
(A2) $((\phi \rightarrow(\chi \rightarrow \psi)) \rightarrow((\phi \rightarrow \chi) \rightarrow(\phi \rightarrow \psi)))$
(A3) $((\neg \phi \rightarrow \neg \chi) \rightarrow(\chi \rightarrow \phi))$
(A4) $\left(\forall v_{i} \phi\left(v_{i}\right) \rightarrow \phi(t)\right)$, where $v_{i}$ is a variable letter and $t$ is a term which can be sensibly substituted for $v_{i}$, that is, it contains no variable letter $v_{j}$ such that $v_{i}$ occurs free in $\phi$ in the scope of a quantifier $\forall v_{j}$,
(A5) $\left(\forall v_{i}(\phi \rightarrow \chi) \rightarrow\left(\phi \rightarrow \forall v_{i} \chi\right)\right)$, for $v_{i}$ a variable letter, provided $v_{i}$ does not occur free in $\phi$,
(A6) $\forall v_{i}\left(v_{i}=v_{i}\right)$,
(A7) if $F$ and $G$ are atomic formulae, where $G$ is obtained from $F$ by replacing some, but not necessarily all, occurrences of $v_{i}$ by $v_{j}$, then $\left(\left(v_{i}=v_{j}\right) \rightarrow(F \rightarrow G)\right)$.

Definition 1.2.2. The rules of inference are the following, where $\phi$ and $\chi$ are any formulae and $x$ is any variable letter:
(MP) Modus Ponens: that is, from $\phi$ and $\phi \rightarrow \chi$ deduce $\chi$;
(Gen) Generalisation: from $\phi$ deduce $\forall v_{i} \phi$.
This system is slightly different from that in the B1.1 Logic course. However the Completeness Theorem is true for both, and they have exactly the same sets of theorems.
Definition 1.2.3. If $\Gamma$ is a (possibly empty) set of formulae, and $\phi$ is a formula, we say that $\phi$ can be proved from $\Gamma$, and write $\Gamma \vdash \phi$, if and only if there exists a finite sequence $\phi_{1}, \ldots, \phi_{n}$ of formulae such that $\phi_{n}=\phi$, and for each $i$, $\phi_{i}$ is an element of $\Gamma$, or a logical axiom, or else it is deduced from previous members of the sequence using a rule of inference.

We will need to refer to the details of the system occasionally.

### 1.3. Interpretation

We will usually interpret $\mathscr{L}$ as applying to the semiring $(\mathbb{N}, 0,1,+, \cdot)$, where $\overline{0}$ is interpreted as referring to $0,{ }^{+}$as referring to the successor function $n \mapsto n+1$ (so that $\bar{n}$ refers to $n$ ), and the function symbols $f, f^{\prime}$ as referring, respectively, to addition and multiplication; and we interpret $\mathscr{L}_{E}$ as referring to the expansion obtained by adding the exponentiation operation, when $f^{\prime \prime}$ will refer to exponentiation.

For terms $\sigma$ and $\tau$, we normally rewrite $(\sigma f \tau)$ as $\sigma+\tau,\left(\sigma f^{\prime} \tau\right)$ as $\sigma . \tau$, and ( $\sigma f^{\prime \prime} \tau$ ) as $\sigma^{\tau}$.

We will normally define truth with respect to this interpretation, though we will sometimes remember to say "true in $\mathbb{N}$ " to make this a little clearer. We will occasionally refer to other interpretations.

Definition 1.3.1. A subset $A$ of $\mathbb{N}^{k}$ is definable if and only if there exists a formula $\phi\left(v_{1}, \ldots, v_{k}\right)$ with only $v_{1}, \ldots, v_{k}$ free, such that $\phi\left(\overline{n_{1}}, \ldots, \overline{n_{k}}\right)$ is true if and only if $\left(n_{1}, \ldots, n_{k}\right) \in A$. We say that $A$ is provably definable from a set of assumptions $S$ if $S \vdash \phi\left(\overline{n_{1}}, \ldots, \overline{n_{k}}\right)$ if $\left(n_{1}, \ldots, n_{k}\right) \in A$, and $S \vdash \neg \phi\left(\overline{n_{1}}, \ldots, \overline{n_{k}}\right)$ if $\left(n_{1}, \ldots, n_{k}\right) \notin A$.

A function $g: \mathbb{N}^{k} \rightarrow \mathbb{N}$ is definable if and only if the set $A=\left\{\left(n_{1}, \ldots, n_{k}, g\left(n_{1}, \ldots, n_{k}\right)\right)\right.$ : $\left.n_{1}, \ldots, n_{k} \in \mathbb{N}\right\}$ is definable, and is weakly provably definable from a set of assumptions $S$ if $A$ is provably definable. $f$ is provably definable from $S$ if for all $n_{1}, \ldots, n_{k} \in \mathbb{N}$, $S \vdash \forall v_{1}\left(\phi\left(\overline{n_{1}}, \ldots, \overline{n_{k}}, v_{1}\right) \leftrightarrow v_{1}=\overline{g\left(n_{1}, \ldots, n_{k}\right)}\right)$, where $\phi$ is the formula defining $A$.

## 2. Peano arithmetic

### 2.1. The Peano axioms

We will be considering a number of axiom schemes for arithmetic on $\mathbb{N}$ of different strengths. The most famous, and most commonly used, is:
Definition 2.1.1. We will denote by PA (Peano Arithmetic) the following list of statements (all of which are expressible in $\mathscr{L}$ ):

1. $\forall v_{i} \neg v_{i}{ }^{+}=\overline{0} ; \forall v_{i} \forall v_{j}\left(v_{i}{ }^{+}=v_{j}^{+} \rightarrow v_{i}=v_{j}\right)$.
( $n \mapsto n^{+}$is an injection from $\mathbb{N} \leftrightarrow \mathbb{N} \backslash\{0\}$ ).
2. $\forall v_{i} v_{i}+\overline{0}=v_{i}$ and $\forall v_{i} v_{i} .0=0$.
3. $\forall v_{i} \forall v_{j} v_{i}+v_{j}^{+}=\left(v_{i}+v_{j}\right)^{+}$and $\forall v_{i} \forall v_{j} v_{i} \cdot v_{j}^{+}=\left(v_{i} \cdot v_{j}\right)+v_{i}$.
4. i. $\forall v_{i} \overline{0} \leq v_{i} ; \forall v_{i} \forall v_{j}\left(v_{i} \leq v_{j} \leftrightarrow\left(v_{i}=v_{j} \vee v_{i}{ }^{+} \leq v_{j}\right)\right)$;
ii. $\forall v_{i} v_{i} \leq v_{i}$;
iii. $\forall v_{i} \forall v_{j}\left(\left(\left(v_{i} \leq v_{j}\right) \wedge\left(v_{j} \leq v_{i}\right)\right) \rightarrow v_{i}=v_{j}\right)$;
iv. $\forall v_{i} \forall v_{j} \forall v_{k}\left(\left(v_{i} \leq v_{j} \wedge v_{j} \leq v_{k}\right) \rightarrow\left(v_{i} \leq v_{k}\right)\right)$;
v. $\forall v_{i} \forall v_{j}\left(v_{i} \leq v_{j} \vee v_{j} \leq v_{i}\right)$.
( $\leq$ is a total order, with initial element 0 , and $n^{+}$is the immediate successor of $n$.)
5. (Induction Schema): For any formula $\phi\left(v_{1}\right)$ of $\mathscr{L}$, the following is an axiom: if $\phi(0)$, and if for all $n, \phi(n)$ implies $\phi\left(n^{+}\right)$, then $\forall n \phi(n)$.

Formally:

$$
\left(\left(\phi(\overline{0}) \wedge\left(\forall v_{1} \phi\left(v_{1}\right) \rightarrow \phi\left(v_{1}^{+}\right)\right)\right) \rightarrow \forall v_{1} \phi\left(v_{1}\right)\right) .
$$

Exercise 2.1.2. From $P A$ it is provable that the successor function $n \mapsto n^{+}$is onto $\mathbb{N} \backslash\{0\}$.
EXERCISE 2.1.3. From $P A$ it is provable that if $m$ and $n$ are natural numbers, then $m \leq n$ iff $\exists k m+k=m$.

The strongest axiom set for arithmetic we'll be using is the following.
Definition 2.1.4. We will denote by PAE (Peano Arithmetic with Exponentiation) PA, augmented by the following statements:
$2^{\prime}: \forall v_{i} v_{i}^{\overline{0}}=\overline{1}$.
$3^{\prime}: \forall v_{i}, v_{j} v_{i}^{v_{j}^{+}}=v_{i}^{v_{j}} \cdot v_{i}$.
$5^{\prime}$ : instances of the induction schema involving formulae $\phi\left(v_{1}\right)$ belonging to $\mathscr{L}_{E}$ but not to $\mathscr{L}$.

### 2.2. Gödel numbering

Notation 2.2.1. We will from time to time write numbers in base 13. When we do that, we will use the symbol $A$ to refer to ten, $B$ to refer to eleven, and $C$ to refer to twelve.

When confusion is likely, we'll use a subscript ${ }_{13}$ to indicate that a number is to be read in base 13, and ${ }_{10}$ to indicate that it should be read in base 10.

The alphabet of $\mathscr{L}$ has thirteen symbols, and we will assign numbers 0 to 12 to them. A string has a Gödel number, which is got by replacing each symbol by a digit in the set $0,1,2,3,4,5,6,7,8,9, A, B, C$, and then interpreting the result as a number in base 13.
(Thirteen is convenient partly because it's prime, and partly because with more symbols, it's easier to work out how to write stuff. We could get away with two symbols, by representing each of the above thirteen symbols by a different string of four 0's and 1's.)

More formally:
Definition 2.2.2. Gödel numbers are assigned to the symbols of the language $\mathscr{L}_{E}$ as follows:

| + | $\overline{0}$ | $($ | $)$ | $f$ | $\prime$ | $v$ | $\neg$ | $\rightarrow$ | $\forall$ | $=\mid$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | 1 | 2 | 3 | 4 | 4 | 5 | $\#$ | 7 | 8 | 9 |

—where all numbers are to be read in base 13. If $s$ is a symbol of $\mathscr{L}_{E}$, then its Gödel number may be written as $\ulcorner s\urcorner$.

The Gödel number of an expression of $\mathscr{L}_{E}$ is obtained by writing the Gödel numbers of the individual symbols in order, and reading the result in base 13; that is, if $\phi=s_{0} s_{1} \ldots s_{r}$, where the $s_{i}$ are symbols of $\mathscr{L}$ and $s_{0}$ is not ${ }^{+}$, then:

$$
\ulcorner\phi\urcorner=\left(\left\ulcorner s_{0}\right\urcorner\left\ulcorner s_{1}\right\urcorner \ldots\left\ulcorner s_{r}\right\urcorner\right)_{13} .
$$

One can quickly convince oneself that

$$
\left(\left\ulcorner s_{0}\right\urcorner\left\ulcorner s_{1}\right\urcorner \ldots\left\ulcorner s_{r}\right\urcorner\right)_{13}=\left\ulcorner s_{0}\right\urcorner 13^{r}+\left\ulcorner s_{1}\right\urcorner 13^{r-1}+\cdots+\left\ulcorner s_{r}\right\urcorner .
$$

Definition 2.2.3. The Gödel number of a term or formula is defined as in the previous definition. The Gödel number of a sequence of terms or formulae is obtained by separating the formulae by \#, so that

$$
\left\ulcorner\left(\phi_{1}, \ldots, \phi_{k}\right)\right\urcorner=\left\ulcorner \# \phi_{1} \# \phi_{2} \# \ldots \# \phi_{k} \#\right\urcorner .
$$

NOTE: All we really require of our system of Gödel numbering is that there should exist a definable (in $\mathscr{L}_{E}$ ) function o such that $\ulcorner\phi \psi\urcorner=\ulcorner\phi\urcorner \triangleright\ulcorner\psi\urcorner$, and such that the function $n \mapsto \overline{\ulcorner n\urcorner}$ is definable.

We commit the abuse of using symbols such as $x, y, m, n$ and so forth for $v_{0}, v_{1}$ and so forth.

### 2.3. The arithmetical hierarchy

We classify formulae in prenex normal form according to the string of quantifiers at the front.
Definition 2.3.1. A bounded quantifier is of the form $\exists m \leq n$ or $\forall m \leq n$ (strictly not in our language, but $\exists m \leq n \phi$ can be expressed by $\exists m(m \leq n \wedge \phi)$, and $\forall m \leq n \phi$ can be expressed by $\forall m(m \leq n \rightarrow \phi)$.)

Definition 2.3.2. A formula is $\Sigma_{0}, \Pi_{0}$, or $\Delta_{0}$, if it contains no unbounded quantifiers.
If $\phi$ is $\Sigma_{n}$, then $\forall m \phi$ is $\Pi_{n+1}$, and if $\phi$ is $\Pi_{n}$, then $\exists m \phi$ is $\Sigma_{n+1}$.
We say that a formula $\phi$ is provably $\Sigma_{n}$ (or) $\Pi_{n}$ if there is a formula $\phi^{\prime}$ which is respectively $\Sigma_{n}$ or $\Pi_{n}$, such that $\phi \leftrightarrow \phi^{\prime}$ is a theorem. If $S$ is a set of axioms, then we say $\phi$ is provably $\Sigma_{n}$ or $\Pi_{n}$ with respect to $S$ if there is a formula $\phi^{\prime}$ which is respectively $\Sigma_{n}$ or $\Pi_{n}$, such that $S \vdash \phi \leftrightarrow \phi^{\prime}$. If $\phi$ is provably $\Sigma_{n}$ and provably $\Pi_{n}$, then we say that it is $\Delta_{n}$; similarly with $\Delta_{n}$ with respect to $S$.

We often omit the word "provably".
Example 2.3.3. As an example, $(\neg m \leq n \vee \exists k m+k=n)$ is not $\Sigma_{0}$, but is provably $\Sigma_{0}$, since it is provably equivalent to $\exists k \leq n(\neg m \leq n \vee m+k=n)$.

Proposition 2.3.4. The set of formulae that is provably $\Sigma_{n}$ is closed under conjunction, disjunction, bounded quantification and, if $n>0$, existential quantification.

The set of formulae that is provably $\Pi_{n}$ is closed under conjunction, disjunction, bounded quantification and, if $n>0$, universal quantification.

Proof: Exercise.

### 2.4. Results concerning expressibility

Definition 2.4.1. A set $T$ of expressions of $\mathscr{L}_{E}$ is definable if and only if there exists a formula $\phi(x)$ such that $\phi(\overline{\ulcorner\psi\urcorner})$ is true if and only if $\psi$ belongs to $T$.

If $S$ is a set of sentences of $\mathscr{L}_{E}$, and $T$ is a set of expressions, we will say that $T$ is provably definable from $S$ if for some formula $\phi, \phi(\overline{\ulcorner \urcorner\urcorner)}$ is provable from $S$ if and only if $\psi$ belongs to $T$, and $\neg \phi(\overline{\ulcorner\psi\urcorner)}$ is provable from $S$ if and only if $\psi$ does not belong to $T$.

Definition 2.4.2. A property $\phi$ of natural numbers or of finite sequences of natural numbers is expressible iff the set $\{n: \mathbb{N} \vDash \phi(\bar{n})\}$ is definable.

Proposition 2.4.3. Any finite set of expressions is definable, and is indeed provably definable (from $\varnothing$ ).

Lemma 2.4.4. Express $m<n$ as $m \leq n \wedge \neg m=n$. This is $\Sigma_{0}$.
$m \mid n$ is provably $\Sigma_{0}$.
Write $[m, n]$ for $\frac{1}{2}(m+n+1)(m+n)+m$. The function $(m, n) \mapsto[m, n]$ is a bijection between $\mathbb{N} \times \mathbb{N}$ and $\mathbb{N}$, and the statement " $k=[m, n]$ " is provably $\Sigma_{0}$.

Lemma 2.4.5. The statement that $r$ is the largest number such that $13^{r} \leq n$ is expressible in $\Sigma_{0}$.

Proof: We express it as follows: $\overline{13}^{r} \leq \bar{n} \wedge \neg \overline{13}^{r^{+}} \leq \bar{n}$.

Lemma 2.4.6. The statement that $n$ is the result of concatenating $k$ and $l$ is expressible in $\Sigma_{0}$.

Proof: We express the statement as follows:
$k \neq 0$; also $l=0$ and $n=13 . k$, or $l \neq 0$ and there exists $r \leq l$ such that $r$ is the greatest number such that $13^{r} \leq l$, and $n=13^{r^{+}} k+l$.

It's straightforward to get concatenations of more than two.
Lemma 2.4.7. The following can be expressed in complexity $\Sigma_{0}$ :

1. $k$ is an initial part of $n$;
2. $l$ is a final part of $n$;
3. $k$ is a substring of $n$.

Proof: $k$ is an initial part of $n$ : there exists $l \leq n$ such that $n$ is the result of concatenating $k$ and $l$. We write this as $k B n$.
$l$ is a final part of $n$ : there exists $k \leq n$ such that $n$ is the result of concatenating $k$ and $l$. We write this as $k E n$.
$k$ is a substring of $n$ : there exists $l \leq n$ such that $l$ is an initial part of $n$ and $k$ is a final part of $l$. We write this as $k P n$.

These are all provably $\Sigma_{0}$.
Lemma 2.4.8. The following can be expressed in complexity $\Sigma_{0}$ :

1. The first element of the string with Gödel number $n$ has Gödel number m (where $n$ is not zero, and in this case necessarily, $m$ is not zero);
2. The last element of the string with Gödel number $n$ has Gödel number m.

Proof: The first element of the string with Gödel number $n$ has Gödel number $m$ can be expressed thus: $0<m, m<13$, and for some $k \leq n, n$ is the result of concatenating $m$ and $k$.

The last element of the string with Gödel number $n$ has Gödel number $m: m=0$ and $13 \mid n$, or $0<m<13$ and there exists $k \leq n$ such that $n$ is the result of concatenating $k$ and $m$.

These statements are provably $\Sigma_{0}$.
Lemma 2.4.9. The following statement is expressible in complexity $\Sigma_{0}$ :
$n$ codes a sequence of (non-empty) expressions, the last member of which is $\sigma$.
Proof: We may express " $n$ codes a sequence of (non-empty) expressions, the last member of which is $\sigma$ " as follows: $\sigma$ contains no $\#$, and either $n$ results from concatenating $\ulcorner \#\urcorner$, $\ulcorner\sigma\urcorner$, and $\ulcorner \#\urcorner$, or there exists $a \leq n$ such that $a$ has first and last characters \#, the string \#\# does not occur in $a$, and $n$ results from concatenating $\ulcorner a\urcorner,\ulcorner\sigma\urcorner$ and $\ulcorner$ \# .

This is $\Sigma_{0}$.

## 3. Recursive functions

In this section we pin down exactly what sets and functions can be described in complexity $\Delta_{1}$ and $\Sigma_{1}$.

### 3.1. Recursive functions

Definition 3.1.1. The primitive recursive functions are the smallest class of functions from finite powers of $\mathbb{N}$ to $\mathbb{N}$ with the following properties.

1. The constant function $n \mapsto 0$ is primitive recursive.
2. The successor function $n \mapsto n+1$ is primitive recursive.
3. For any positive integer $k$, for any $i \leq k$, the projection function $\left(n_{1}, \ldots, n_{k}\right) \mapsto n_{i}$ is primitive recursive.
4. Composition: the function $h\left(n_{1}, \ldots, n_{k}\right)=g\left(f_{1}\left(n_{1}, \ldots, n_{k}\right), \ldots, f_{m}\left(n_{1}, \ldots, n_{k}\right)\right)$ is primitive recursive, when $g$ and all $f_{j}$ are primitive recursive.
5. Primitive recursion: $f$ is primitive recursive, where $f\left(n_{1}, \ldots, n_{k}, 0\right)=g\left(n_{1}, \ldots, n_{k}\right)$, and for all $n$, $f\left(n_{1}, \ldots, n_{k}, n+1\right)=h\left(n_{1}, \ldots, n_{k}, n, f\left(n_{1}, \ldots, n_{k}, n\right)\right)$, where $g$ and $h$ are primitive recursive.

EXAMPLE 3.1.2. The addition function $A:(m, n) \mapsto m+n$ is primitive recursive.
Proof: Let $h(m, n, k)=k+1$ (this is primitive recursive, since it is the composition of a projection function with the successor function).

Let $g(m)=m$ (the identity on $\mathbb{N}$ is a projection, so is primitive recursive).
Then for all $m$, we define $A$ by primitive recursion so that $A(m, 0)=g(m)$, and for all $m$ and $n, A(m, n+1)=h(m, n, A(m, n))$.

Example 3.1.3. The modified subtraction function $S$ defined so that $S(m, n)=m-n$ if $m \geq n$ and $S(m, n)=0$ if $m<n$, is primitive recursive.

Multiplication and exponentiation are primitive recursive.
We obtain the recursive partial functions by also using the minimalisation operator, which, given a function $g$, returns the least $n$ such that $g\left(n_{1}, \ldots, n_{k}, n\right)=0$ if there is one, and is undefinable otherwise.
Definition 3.1.4. The recursive functions are the smallest class of partial functions from finite powers of $\mathbb{N}$ to $\mathbb{N}$ with the following properties, where we use the notation $f \simeq g$ to mean " $f$ and $g$ have the same domain, and on that domain they are equal".

1. The constant function $n \mapsto 0$ is recursive.
2. The successor function $n \mapsto n+1$ is recursive.
3. For any positive integer $k$, for any $i \leq k$, the projection function $\left(n_{1}, \ldots, n_{k}\right) \mapsto n_{i}$ is recursive.
4. The function $h\left(n_{1}, \ldots, n_{k}\right) \simeq g\left(f_{1}\left(n_{1}, \ldots, n_{k}\right), \ldots, f_{m}\left(n_{1}, \ldots, n_{k}\right)\right)$ is recursive, when $g$ and all $f_{j}$ are recursive.
5. Primitive recursion: $f$ is recursive, where $f\left(n_{1}, \ldots, n_{k}, 0\right) \simeq g\left(n_{1}, \ldots, n_{k}\right)$, and for all $n, f\left(n_{1}, \ldots, n_{k}, n+1\right) \simeq h\left(n_{1}, \ldots, n_{k}, n, f\left(n_{1}, \ldots, n_{k}, n\right)\right)$, where $g$ and $h$ are recursive.
6. Minimalisation: suppose that $g\left(n_{0}, n_{1}, \ldots, n_{k}\right)$ is a recursive function. Then the partial function $f\left(n_{1}, \ldots, n_{k}\right)$, defined to be the value of $n$ such that $g\left(n, n_{1}, \ldots, n_{k}\right)=0$ and for all $m<n, g\left(m, n_{1}, \ldots, n_{k}\right)>0$, if this exists, and undefined if it does not, is recursive. We write $f$ as $\mu m g\left(m, n_{1}, \ldots, n_{k}\right)$.
EXAMPLE 3.1.5. Ackerman's function is recursive but not primitive recursive:
$\psi(0, n)=n+1$
$\psi(m+1,0)=\psi(m, 1)$

$$
\psi(m+1, n+1)=\psi(m, \psi(m+1, n)) .
$$

Proof: (Non-examinable) Ingenious, using induction on the complexity of the demonstration that a function is primitive recursive to show that if $f(n)$ is primitive recursive, then there exists $m$ such that the function $m \mapsto \psi(m, n)$ dominates $f(n)$ (in the sense that for all but finitely many $n, \psi(m, n)>f(n))$; one then deduces that $n \mapsto \psi(n, n)$ is not primitive recursive and that therefore $\psi$ isn't either.

It grows rather fast.
Empirical fact 3.1.6. (Church's Thesis) The recursive partial functions $f\left(x_{1}, \ldots, x_{k}\right)$ are precisely those that can in principle be calculated by a computer algorithm (that is, such that there is an algorithm that when presented with input $\left(a_{1}, \ldots, a_{k}\right)$ for which $f\left(a_{1}, \ldots, a_{k}\right)$ is defined, outputs $f\left(a_{1}, \ldots, a_{k}\right)$ after a finite time, and when presented with input for $\left(a_{1}, \ldots, a_{k}\right)$ for which $f\left(a_{1}, \ldots, a_{k}\right)$ is undefined, runs for ever without halting).

Primitive recursion is expressible in $\mathscr{L}_{E}$.
Theorem 3.1.7. Every primitive recursive function is definable in complexity $\Sigma_{1}$.
Proof: We argue by induction on the length of the demonstration that a function is primitive recursive. The only difficult step is when we use primitive recursion. Then we appeal to the following lemma.
Lemma 3.1.8. Suppose that $g: \mathbb{N}^{k} \rightarrow \mathbb{N}$ and $h: \mathbb{N}^{k+2} \rightarrow \mathbb{N}$ are functions that can be defined in complexity $\Sigma_{1}$.

Then the function $f$ defined by primitive recursion from $g$ and $h$, that is to say, defined so that:

1. $f\left(n_{1}, \ldots, n_{k}, 0\right)=g\left(n_{1}, \ldots, n_{k}\right)$, and
2. $f\left(n_{1}, \ldots, n_{k}, n+1\right)=h\left(n_{1}, \ldots, n_{k}, n, f\left(n_{1}, \ldots, n_{k}, n\right)\right)$,
is definable in complexity $\Sigma_{1}$.
Proof: Consider the statement $D(y)$, where $y$ is a natural number: " $y$ is the Gödel number of a sequence, the first element of which is $\left.\overline{\left[0, g\left(n_{1}, \ldots, n_{k}\right)\right.}\right]$, and for each $m \leq y$, if $m$ is a member of the sequence, then for all $i, j \leq y$ such that $m=\overline{[i, j]}$, for all $m^{\prime} \leq y$, if $m^{\prime}$ immediately follows $m$ in the sequence, for all $i^{\prime}, j^{\prime} \leq y$ such that $m^{\prime}=\overline{\left[i^{\prime}, j^{\prime}\right]}, i^{\prime}=i+1$ and $j=\left[i, h\left(n_{1}, \ldots, n_{k}, i, j\right)\right]$ ".

This statement is $\Sigma_{1}$, and expresses the idea that $y$ codes a derivation of values of the function $f$ using primitive recursion.

We now express " $z=f\left(n_{1}, \ldots, n_{k}, n\right)$ "as "There exists $y$ such that $D(y)$ holds, and $[n, z]$ occurs in the sequence coded by $y$."

This is $\Sigma_{1}$.
THEOREM 3.1.9. Every recursive partial function is $\Sigma_{1}$-definable, and vice versa.
Proof: $\Rightarrow)$ : Easy once we know primitive recursion is expressible. Minimalisation adds an existential quantifier.
$\Leftarrow)$ : Let $\phi$ be $\Sigma_{0}$ such that $y=f(\mathbf{x}) \leftrightarrow \exists z \phi(\mathbf{x}, y, z)$.
Roughly speaking, search for $y$ and $z$-or for $[y, z]$-such that $\phi(\mathbf{x}, y, z)$. If one exists, stop and output $y$. If not, return $\perp$.

How do we tell if $\phi(\mathbf{x}, y, z)$ ?

We define primitive recursive $h_{\psi}$ which tells whether $\psi$ is true or not by recursion on $\Sigma_{0} \psi$ as follows. We will define $h_{\psi}$ to have $k$ arguments, where $k$ is largest such that $v_{k}$ occurs free in $\psi$.
$h_{v_{i}=v_{j}}\left(n_{0}, \ldots, n_{k}\right)=S\left(1, S\left(n_{i}, n_{j}\right)+S\left(n_{j}, n_{i}\right)\right)$, where $k \geq j, i$,
$h_{v_{i} \leq v_{j}}\left(n_{0}, \ldots, n_{k}\right)=S\left(1, S\left(n_{i}, n_{j}\right)\right)$ where $k \geq j, i$,
$h_{v_{i}=\bar{n}}\left(n_{0}, \ldots, n_{i}\right)=S\left(1, S\left(n_{i}, n\right)+S\left(n, n_{i}\right)\right)$,
and so on through all the other kinds of atomic formula.
$h_{\neg \psi}\left(n_{0}, \ldots, n_{k}\right)=S\left(1, h_{\psi}\left(n_{0}, \ldots, n_{k}\right)\right)$.
$h_{\phi \rightarrow \psi}\left(n_{0}, \ldots, n_{k}\right)=S\left(1, h_{\phi}\left(n_{1}, \ldots, n_{i}\right) . S\left(1, h_{\psi}\left(n_{1}, \ldots, n_{j}\right)\right)\right)$ where $k$ is the larger of $i$ and $j$.

If $i, j \leq k$, and either $i \neq j$ and $l=k+2$ or $i=j$ and $l=k+1$, then if $i<j$, then $h_{\forall v_{i} \leq v_{j} \phi}\left(n_{0}, \ldots, n_{k}\right)=\max _{m \leq n_{j}} h_{\phi}\left(n_{0}, \ldots, n_{i-1}, m, n_{i+1}, \ldots, n_{j-1}, n_{j}, \ldots\right)$, with similar definitions in the cases $i=j$ and $j<i$.
$h_{\exists v_{i} \leq v_{j} \phi}\left(n_{0}, \ldots, n_{k}\right)$ is defined in a similar way using min instead of max.
Similarly for formulae beginning $\forall v_{i} \leq \bar{n}$ and $\exists v_{i} \leq \bar{n}$.
Then express " $f(\mathbf{x})=y$ " as: " $y$ is the first component of $[y, z]$, where $n=[y, z]$ is least such that $S\left(1, h_{\phi}(\mathbf{x}, y, z)\right)=0$ " (that is, such a pair $N=[Y, Z]$ exists, and of all the $N^{\prime}=\left[Y^{\prime}, Z^{\prime}\right] \leq N$ having the right properties, $n$ is the least). (Recall that " $n=[y, z]$ " is $\Delta_{0}$.)

Definition 3.1.10. A set is recursive if its characteristic function $\chi_{A}$ is recursive, and recursively enumerable if the partial function $\pi_{A}$ which is 1 on the set and undefined off, is recursive.

Theorem 3.1.11. Equivalently, a set is recursively enumerable iff it is $\Sigma_{1}$, and recursive iff it is $\Delta_{1}$.

Proof: If $A$ is recursively enumerable, then $\pi_{A}$ is recursive, and hence $\Sigma_{1}$-definable. Then $A$ is defined by the statement " $\pi_{A}(\bar{n})=\overline{1}$ ", which is $\Sigma_{1}$.

Suppose $A$ is defined by a $\Sigma_{1}$ formula $\phi$.
Then we define $\pi_{A}$ thus: a pair $(n, m)$ belongs to the graph of $\pi_{A}$ if and only if $\phi(\bar{n})$ and $\bar{m}=\overline{1}$. This statement can be expressed in $\Sigma_{1}$.

Suppose $A$ is recursive. Then $\pi_{A}=\pi_{\{1\}} \circ \chi_{A}$, which is recursive, and $\pi_{A^{c}}=\pi_{\{0\}} \circ$ $\chi_{A}+1$, which is also recursive.

By the above reasoning, both $A$ and its complement are $\Sigma_{1}$-definable.
Hence $A$ is $\Delta_{1}$.
Also by the above, if $A$ is $\Delta_{1}$, then $A$ and its complement are both $\Sigma_{1}$. Let us suppose that $A$ is defined by $\phi$ and its complement by $\psi$.

Then we may define $\chi_{A}$ in $\Sigma_{1}$ as follows: The formula $\theta(n, m)$ asserting that ( $n, m$ ) belongs to the graph of $\chi_{A}$ expresses: "either $\phi(\bar{n})$ and $\bar{m}=\overline{1}$, or $\psi(\bar{n})$ and $\bar{m}=\overline{0}$ ".

So $\chi_{A}$ is $\Sigma_{1}$-definable, and therefore recursive.
Corollary 3.1.12. $A$ set $A$ is recursive if and only if both $A$ and its complement are recursively enumerable.
Corollary 3.1.13. A subset $A$ of $\mathbb{N}$ is recursively enumerable if and only if it the range of some recursive partial function.

Proof: If $A$ is recursively enumerable, then define $f(n)$ to be $n . \pi_{A}(n)$. This is recursive, and has range $A$.

Now suppose that $f$ is a recursive partial function with range $A$. Since $f$ is recursive, the statement " $(n, m)$ is in the graph of $f$ " is $\Sigma_{1}$-definable. Now the statement " $(n, m)$ is in the graph of $\pi_{A}$ " may be expressed as: "there exists $k$ such that $(k, \bar{n})$ is in the graph of $f$, and $\bar{m}=\overline{1}$.

### 3.2. Defining exponentiation

Lemma 3.2.1. The property of being a power of 13 can be defined in $\mathscr{L}$ in complexity $\Sigma_{0}$.
Proof: We express " $n$ is a power of 13 " as: " $\bar{n}=\overline{1}$, or $\overline{13} \mid \bar{n}$, and if $p<\bar{n}$ and $p \mid \bar{n}$ and $\neg \overline{13} \mid p$, then $p=\overline{1} "$.

Lemma 3.2.2. The statement " $n$ is the smallest power of 13 greater than $m$ " can be expressed in $\mathscr{L}$ in complexity $\Sigma_{0}$.
Proof: We express it as " $\bar{n}$ is a power of $\overline{13}$ and $\bar{n}$ is greater than $\bar{m}$ and for all $k \leq \bar{n}$, if $k$ is a power of $\overline{13}$ greater than $\bar{m}$, then $k=\bar{n}$ ".

Lemma 3.2.3. We can express the concatenation operator $(m, n) \mapsto m^{\wedge} n$ in $\mathscr{L}$ in complexity $\Sigma_{0}$.
Proof: We express " $k=m^{\wedge} n$ " as "there exists $l \leq \bar{k}$ such that $l$ is the smallest power of $\overline{13}$ greater than $\bar{n}$, and $\bar{k}=\bar{m} \cdot \bar{l}+\bar{n}$.

Corollary 3.2.4. The statement $k=m^{n}$, for $m$, $n$ and $k$ natural numbers, is definable in $\mathscr{L}$, and is indeed $\Delta_{1}$.
Proof: Exponentiation is primitive recursive.

## 4. Defining provability

### 4.1. Defining expressibility

Lemma 4.1.1. " $n=\ulcorner\bar{m}\urcorner$ " is expressible in $\Delta_{1}$.
Proof: We can express it as follows: $n=13^{m \overline{\ulcorner 0}}+\sum_{i=0}^{m-1} 13^{i\ulcorner+\urcorner}=13^{m \overline{\Gamma 0}}$ since $\ulcorner+\urcorner=0$.

Corollary 4.1.2. " $n$ is the Gödel number of a numeral term" is expressible in $\Delta_{1}$.
Proof: We say: there exists $m \leq n$ such that $n=\overline{\ulcorner m\urcorner}$.
Lemma 4.1.3. " $n=\left\ulcorner v_{m}\right\urcorner$ " is expressible in $\Delta_{1}$.
Proof: The following are all expressible in $\Sigma_{0}$ : the first character of the expression that $n$ codes for, is $v$, and all the other characters are '; and $m$ is largest such that $13^{m} \leq n$.
Corollary 4.1.4. " $n$ is the Gödel number of some variable term" is expressible in $\Delta_{1}$.
Proof: We say: there exists $m \leq n$ such that $n=\left\ulcorner v_{m}\right\urcorner$.
Lemma 4.1.5. " $n$ is the Gödel number of a term" is expressible in $\Delta_{1}$.

Proof: We argue that there is an algorithm which decides, for any $n$, whether or not $n$ is the Gödel number of a term. It will then follow that the set of Gödel numbers of terms is recursive and therefore $\Delta_{1}$.

The algorithm will proceed as follows (and works by recursion).
If $n$ is the Gödel number of a numeral term or a variable term, stop, and give the answer "yes".

If there exists $m<n$ such that $m$ is the Gödel number of a term, and $n=13 . m$, then stop, and output "yes".

If there exist $k, l<m$ such that $k$ and $l$ are the Gödel numbers of terms, and $n$ is the concatenation of $\left\ulcorner( \urcorner, k\right.$, any of $\ulcorner f\urcorner,\left\ulcorner f^{\prime}\right\urcorner$, or $\left\ulcorner f^{\prime \prime}\right\urcorner$, and $)\urcorner$, then stop and output "yes".

The procedure outlined so far takes only a finite amount of time.
If none of the above are true, then stop and output "no".
Lemma 4.1.6. The notion " $n$ is the Gödel number of an atomic formula" is expressible in $\Delta_{1}$.

Proof: We say the following: there exist $k \leq n$ and $l \leq n$ such that $k$ and $l$ are the Gödel numbers of terms, and $n$ is the concatenation of $k$, one of $\ulcorner=\urcorner$ or $\ulcorner\leq\urcorner$, and $l$.

Lemma 4.1.7. The notion " $n$ is the Gödel number of a formula" is expressible in $\Delta_{1}$.
Proof: Similar to the corresponding argument for terms.
Lemma 4.1.8. The notion " $n$ is the Gödel number of a logical axiom" is expressible in $\Delta_{1}$.

Proof: This follows if there is an algorithm which, for any $n$, determines whether or not $n$ is the Gödel number of a logical axiom.

This is clearly possible. For example, to decide whether $n$ is the Gödel number of an instance of (A1), all we have to do it to find out whether there exist $k, l<n$ such that $k$ and $l$ are Gödel numbers of formulae, and $n$ is the concatenation of $\ulcorner( \urcorner, k,\ulcorner( \urcorner, l,\ulcorner\rightarrow\urcorner, k$, $)\urcorner$ and $)\urcorner$.

### 4.2. Defining proofs and provability

Lemma 4.2.1. The statement " $n$ is the Gödel number of a formula, of which $m$ is the Gödel number of a proof from assumptions $S "$ may be expressed by $\Delta_{i}$ formula proof $_{S}(\bar{n}, \bar{m})$, if $S$ is definable in $\Delta_{i}$ for $i \geq 1$.

Proof: We define $\operatorname{proof}_{S}(\bar{n}, \bar{m})$ as follows.
" $n$ is the Gödel number of a formula. $m$ codes a sequence whose last member is $n$. Whenever $c$ is a member of this sequence, then either $c$ codes an axiom, or an assumption, or there exist earlier members $a$ and $b$ of the sequence coding sequences which are connected to $c$ by a rule of inference."

Lemma 4.2.2. Suppose that $S$ is a set of assumptions definable in $\Sigma_{i}$, where $i \geq 1$.
Then there is a $\Sigma_{i}$ formula $\operatorname{Pr}_{S}(\bar{n})$ which holds if and only if $n$ is the Gödel number of a formula provable from $S$.
Proof: $\operatorname{Pr}_{S}(\bar{n})$ can be written as $\exists m \operatorname{proof}_{S}(\bar{n}, m)$.

This is $\Sigma_{i}$.
Lemma 4.2.3. Assume that PAE is consistent, and true in $\mathbb{N}$.
If $S$ is a definable set of assumptions, then $\operatorname{proof}_{S}(\bar{n}, \bar{m})$ is provable from PAE if and only if $n$ is the Gödel number of a formula $\phi$, and $m$ is the Gödel number of a proof of $\phi$ from $S$.

Note that we cannot in general express $\operatorname{Pr}_{S}(\bar{n})$ in complexity $\Delta_{i}$; we do have here an increase in complexity.
Lemma 4.2.4. Assume that PAE is consistent, and true in $\mathbb{N}$.
If $S$ is a provably definable set of assumptions, then $\operatorname{Pr}_{S}(\bar{n})$ is provable from PAE if and only if $n$ is the Gödel number of a formula provable from $S$.

Proof: Recall that $\operatorname{Pr}_{S}(\bar{n})$ can be written as $\exists m \operatorname{proof}_{S}(\bar{n}, m)$.
If $n=\ulcorner\phi\urcorner$, where $\phi$ is provable from $S$, then for some $m$, $\operatorname{proof}_{S}(\bar{n}, \bar{m})$ is true. If it's true, then we can prove from PAE that $m$ is the Gödel number of a proof of $\phi$ from $S$.

Hence we can prove that there exists an $m$ which is the Gödel number of a proof of $\phi$ from $S$; that is, we can prove $\operatorname{Pr}_{S}(\bar{n})$.

Now suppose that $\operatorname{Pr}_{S}(\bar{n})$ is provable from PAE. From our assumption that PAE is true in $\mathbb{N}, \operatorname{Pr}_{S}(\bar{n})$ is true in $\mathbb{N}$ by the Soundness Theorem. Hence by Lemma 4.2.3, $n$ is the Gödel number of a formula provable from $S$.

Definition 4.2.5. Suppose that $S$ is a set of sentences of $\mathscr{L}$. Then a proof predicate for $S$ is a formula $\operatorname{Pr}_{S}(x)$ such that for all formulae $\phi$ of $\mathscr{L}, \phi$ is provable from $S$ if and only if $\operatorname{Pr}_{S}(\phi)$ is provable from PAE.

So what we have just proved is that any $\Delta_{i}$-definable set of formulae has a $\Sigma_{i}$-definable proof predicate.

### 4.3. PA and PAE are definable

Theorem 4.3.1. PA and PAE are definable in $\Delta_{1}$.
Proof: There is an algorithm deciding whether or not a formula is an element of PA or PAE or not.

COROLLARY 4.3.2. $\quad \Delta_{1}$ formulae $\operatorname{proof}_{\mathrm{PA}}(m, n)$ and $\operatorname{proof}_{\mathrm{PAE}}(m, n)$ expressing that $n$ codes a proof of the statement coded by m, in PA and PAE respectively, can be defined, and so can $\Sigma_{1}$ proof predicates $\operatorname{Pr}_{\mathrm{PA}}(n)$ and $\operatorname{Pr}_{\mathrm{PAE}}(n)$.

### 4.4. Eliminating exponentiation

Proposition 4.4.1. Any formula $\phi$ of $\mathscr{L}_{E}$ is provably equivalent from PAE to a formula $\phi^{\prime}$ of $\mathscr{L}$.

Moreover, for $n \geq 1$, if $\phi$ is $\Sigma_{n}$, then $\phi^{\prime}$ can be chosen to be $\Sigma_{n}$, and if $\phi$ is $\Pi_{n}$, then $\phi^{\prime}$ can be chosen to be $\Pi_{n}$.

Proof: Exponentiation is provably $\Delta_{1}$-definable in $\mathscr{L}$.
Proposition 4.4.2. A formula of $\mathscr{L}$ is provable in PAE if and only if it is provable in $P A$.

Proof: Exponentiation can be defined in $\mathscr{L}$ so that formulae of $\mathscr{L}$ equivalent to the axioms of PAE can be written in $\mathscr{L}$.

In more detail, the axioms of PAE not included in PA fall into two classes.
Firstly, instances of the induction schema written in $\mathscr{L}_{E}$. These are rewritten as equivalent instances of the induction schema written in $\mathscr{L}$, which are already axioms of PA.

Secondly, the two statements $\forall v_{1} v_{1}^{\overline{0}}=\overline{1}$ and $\forall v_{1} \forall v_{2}\left(v_{1} v_{2}{ }^{+}=v_{1} v_{2} \cdot v_{1}\right)$. The replacements of these are theorems of PA.
Corollary 4.4.3. Any subset of $\mathbb{N}^{k}$, or any function, that is provably $\Sigma_{n}$ or $\Pi_{n}$ in PAE is similarly in $P A$, for $n \geq 1$.

Corollary 4.4.4. If $n$ is the Gödel number of a formula of $\mathscr{L}$, then the statements $\operatorname{Pr}_{\mathrm{PA}}(\bar{n})$ and $\operatorname{Pr}_{\mathrm{PAE}}(\bar{n})$ are equivalent.

## 5. Diagonalisation and truth

### 5.1. Diagonalisation

Definition 5.1.1. Let $E_{n}$ be the expression (whatever it is) of Gödel number n, assuming this exists.
Definition 5.1.2. $d(n)=E_{n}(\bar{n})$. (d for "diagonal".)
Definition 5.1.3. $\quad D(m, n)$ is the formula $\bar{n}=\overline{\ulcorner d(m)}$.
Lemma 5.1.4. The statements " $m=d(n)$ " and $D(m, n)$ are $\Delta_{1}$.
Theorem 5.1.5. (Diagonal Theorem): given a formula $F(x)$, there exists a formula $C$ such that $C \leftrightarrow F(\overline{\ulcorner C\urcorner})$ is provable in PAE.

This is a fixed-point theorem.
Proof: We consider the formula $F(\overline{\ulcorner d(y)\urcorner})$.
Let $k=\ulcorner\psi\urcorner$.
Let $C=\psi(\bar{k})$.
Now $C$ is $\psi(\bar{k})$, which is equivalent to $F(\overline{\ulcorner d(k)\urcorner})$.
Also $k=\ulcorner\psi\urcorner$, so $C=E_{k}[\bar{k}]=d(k)$. Hence $F(\overline{\ulcorner d(k)\urcorner})=F(\overline{\ulcorner C\urcorner})$.
So $C$ is equivalent to $F(\overline{\ulcorner C})$.

### 5.2. The undefinability of truth

Truth is not expressible.
Theorem 5.2.1. (Tarski's Theorem) There does not exist a formula True $(x)$ such that True $(\overline{\ulcorner\phi})$ is true exactly when $\phi$ is true in $\mathbb{N}$.
Proof: Suppose such a formula to exist.
Then by the Diagonal Lemma, there exists a formula $C$ such that $C$ holds if and only if $\neg \operatorname{True}(\overline{\ulcorner C\urcorner})$.

But then, $\operatorname{True}(\overline{\ulcorner C\urcorner})$ is true if and only if $C$ is true, if and only if $\neg \operatorname{True}(\overline{\ulcorner C\urcorner})$ is true, giving a contradiction.

## 6. Provability

### 6.1. Properties of provability

Theorem 6.1.1. (The First Provability Rule) Suppose $S$ is a provably definable set of assumptions, and $S \vdash \phi$. Then $\mathrm{PA} \vdash \operatorname{Pr}_{S}(\phi)$.

Proof: Write out a formal proof of $\phi$ from $S$. Let $n$ be its Gödel number. Then $\mathrm{PA} \vdash \operatorname{proof}_{S}(\overline{\ulcorner\phi\urcorner}, \bar{n})$.

In more detail, there is an algorithm turning a proof $\left(\phi_{1}, \ldots, \phi_{m}\right)$ of $\phi$ from the set of assumptions $S$ into a proof of proof $_{S}\left(\overline{\ulcorner\phi\urcorner}, \overline{\left\ulcorner\left(\phi_{1}, \ldots, \phi_{m}\right)\right.}\right)$.

For, let $\psi_{S}(x)$ be a formula which provably expresses " $x$ is the Gödel number of a member of $S$ ", that is, $\psi_{S}(x)$ is such that $\mathrm{PA} \vdash \psi_{S}(\bar{n})$ if $n$ is the Gödel number of an element of $S$, and PA $\vdash \neg \psi_{S}(\bar{n})$ otherwise.

Let $\psi_{\text {ax }}(x)$ be a formula which provably expresses " $x$ is the Gödel number of a logical axiom", let $\psi_{\text {rule }}(x, y, z)$ express " $x$ is the Gödel number of a formula which can be obtained by means of a logical rule (MP or Gen) from the formulae with Gödel numbers $y$ and $z$ ". Let $\psi_{\text {last }}(x, y)$ provably express " $x$ is a formula, and is the last member of the sequence of formulae whose Gödel number is $y$ ".

Then $\operatorname{proof}_{S}(x, y)$ expresses the following: " $x$ is the Gödel number of a formula, $y$ is the Gödel number of a sequence of formulae, if $\phi_{i}$ occurs in this sequence, then $\psi_{S}\left(\overline{\left\ulcorner\phi_{i}\right.} \overline{\urcorner}\right)$ or $\psi_{\text {ax }}\left(\overline{\left\ulcorner\phi_{i}\right\urcorner}\right)$ or for some earlier members $\phi_{j}$ and $\phi_{k}, \psi_{\text {rule }}\left(\overline{\left\ulcorner\phi_{i}\right\urcorner}, \overline{\left\ulcorner\phi_{j}{ }^{\urcorner}\right.}, \overline{\left\ulcorner\phi_{k}\right\urcorner}\right)$; and $\psi_{\text {last }}(x, y)$ ".

Now proof ${ }_{S}\left(\overline{\ulcorner\phi}, \overline{\left\ulcorner\left(\phi_{1}, \ldots, \phi_{m}\right)\right\urcorner}\right)$ is true, so we can compile a proof of it from PA by putting together the proofs of the various formulae $\psi_{*}(x, y)$ that we need.

Theorem 6.1.2. (The Second Provability Rule) Suppose $S$ is a definable set of assumptions. $\mathrm{PA} \vdash \operatorname{Pr}_{S}(\phi \rightarrow \psi) \rightarrow\left(\operatorname{Pr}_{S} \phi \rightarrow \operatorname{Pr}_{S} \psi\right)$.

Proof: We show that $\operatorname{PA} \cup\{\operatorname{Pr} \phi, \operatorname{Pr}(\phi \rightarrow \psi)\} \vDash \operatorname{Pr} \psi$, and deduce the result from that.
Suppose that in a model of PA, $n_{1}$ and $n_{2}$ are elements of the model and the statements $\operatorname{proof}\left(\overline{\ulcorner\phi}, n_{1}\right)$ and $\operatorname{proof}\left(\overline{\ulcorner(\phi \rightarrow \psi)\urcorner}, n_{2}\right)$ are true in that model.

Theorem 6.1.3. (The Third Provability Rule) Suppose that $S$ is a provably definable set of assumptions, including PA as a subset.

Then $\mathrm{PA} \vdash \operatorname{Pr}_{S}(\overline{\ulcorner\psi\urcorner}) \rightarrow \operatorname{Pr}_{S}\left(\overline{\left\ulcorner\operatorname{Pr}_{S}(\overline{\ulcorner\psi\urcorner})\right\urcorner}\right)$.
Proof: This is an arithmetised version of the proof of Theorem 6.1.1.
Consider the statement " $m$ is the Gödel number of a proof of $\phi$ from $S$ which is $l$ steps long"; write as $\operatorname{proof}_{S}^{*}(\overline{\ulcorner\phi}, m, l)$. Note that $\operatorname{proof}_{S}(\overline{\ulcorner\phi\urcorner}, m)$ is equivalent to $\exists l \operatorname{proof}_{S}^{*}(\overline{\ulcorner\phi\urcorner}, m, l)$. We will argue inductively that for all $l$, if proof ${ }_{S}^{*}(\overline{\ulcorner\phi\urcorner}, m, l)$ holds, then $\operatorname{Pr}_{S}\left(\overline{\left\ulcorner\operatorname{Pr}_{S}(\overline{\ulcorner\phi})\right\urcorner}\right)$ holds; the argument will proceed by recursively constructing the Gödel number $M$ of a proof in $S$ of $\operatorname{Pr}_{S}(\overline{\ulcorner\phi\urcorner})$, and noting that $\operatorname{proof}_{S}\left(\overline{\left.\operatorname{Pr}_{S}(\overline{\ulcorner\phi})\right\urcorner}, M\right)$ holds.

We will do this in a general model of PA, which means we need to be careful, because in arbitrary models of $\mathrm{PA}, \operatorname{Pr}_{S}(\overline{\ulcorner\psi\urcorner})$ does not necessarily entail $S \vdash \psi$.

Suppose that $\mathfrak{N}$ is a model of PA, and that $\mathfrak{N} \vDash \operatorname{Pr}_{S}(\overline{\ulcorner\phi\urcorner})$.

Then there exist $m, l \in \mathfrak{N}$ such that $\mathfrak{N} \vDash \operatorname{proof}_{S}^{*}(\overline{\ulcorner\phi\urcorner}, m, l)$. In the argument that follows we need to bear in mind that $\mathfrak{N}$ may not be $\mathbb{N}$, and that $m$ and $l$ may not be actual natural numbers; they just have, in $\mathfrak{N}$, some of the first-order properties that natural numbers possess.

We argue using induction on $l$ (this can be formalised in PA, using the induction scheme). We examine the inductive step; the base case is similar, but easier.

Suppose then that in $\mathfrak{N}, l>1$, and that $\mathfrak{N} \vDash \operatorname{proof}_{S}^{*}(i, m, l)$. Suppose, using the inductive hypothesis, that if, in $\mathfrak{N}, j$ is the Gödel number other than the last one of an element of the sequence whose Gödel number is $m$, then there exists $M_{j}$ in $\mathfrak{N}$ such that $\mathfrak{N} \vDash \operatorname{proof}_{S}\left(\overline{\left(\operatorname{Pr}_{S}(i)\right\urcorner}, M_{j}\right)$.

If in $\mathfrak{N}, i$ is the Gödel number of a member of $S$, that is to say, if $\mathfrak{N} \vDash \psi_{S}(i)$, then we let $M_{j}$ be the Gödel number of a proof of $\psi_{S}(i)$.

To justify this step further, recall that in $\mathbb{N}, \psi_{S}(\bar{n})$ is provable if $n$ is the Gödel number of a member of $S$, and $\neg \psi_{S}(\bar{n})$ is provable if not. We shall argue that there is an algorithm which, when presented with input $n$, outputs the Gödel number of a proof of $\psi_{S}(\bar{n})$ if $n \in S$, and outputs the Gödel number of a proof of $\neg \psi_{S}(\bar{n})$ if not. The algorithm goes like this. Examine all formal proofs in $S$, one by one. (They can be listed in a recursive way that permits us to do this). We will eventually encounter either a proof of $\psi_{S}(\bar{n})$, in which case we output its Gödel number; or we encounter a proof of $\neg \psi_{S}(\bar{n})$, in which case we output the Gödel number of that. The existence of this algorithm means that there is a $\Sigma_{1}$-definable function $f_{S}$ inputting $n$ and outputting the Gödel number of the appropriate proof. Suppose that $\chi(x, y)$ expresses " $y=f_{S}(x)$ ". Then if we are in the situation of the previous paragraph, and $\mathfrak{N} \vDash \psi_{S}(i)$, then there exists $M_{i} \in \mathfrak{N}$ such that $\mathfrak{N} \vDash \chi\left(i, N_{i}\right)$. Construct $M_{i}$ by appending $N_{i}$ and a proof of $\psi_{\text {last }}$.

In a similar way, if in $\mathfrak{N}, i$ is the Gödel number of a logical axiom, then let $M_{i}$ be the Gödel number of a proof of $\psi_{\mathrm{ax}}(i)$.

If $i$ is, in $\mathfrak{N}$, the Gödel number of a formula obtained using an application of a rule to formulae earlier in the sequence coded by $n$ whose Gödel numbers are $j$ and $k$, then by the inductive hypothesis there exist elements $M_{j}$ and $M_{k}$ of $\mathfrak{N}$ such that $\mathfrak{N} \vDash \operatorname{proof}_{S}\left(j, M_{j}\right)$ and $\mathfrak{N} \vDash \operatorname{proof}_{S}\left(k, M_{k}\right)$. Then we generate $M_{i}$ by combining $M_{j}$ and $M_{k}$, deleting repeated \#'s as necessary.

THEOREM 6.1.4. Suppose that $S$ is a set of sentences of $\mathscr{L}$, definable from $P$.
For all $\phi, \phi$ is provable in $S$ if and only if $\operatorname{Pr}_{S}(\overline{\ulcorner\phi})$ is true in the standard model $\mathbb{N}$.
Proof: If $\phi$ is provable from $S$, then $\operatorname{Pr}(\overline{\Gamma \phi\urcorner})$ is provable in PA, so $\operatorname{Pr}(\overline{\Gamma \phi\urcorner})$ is true in $\mathbb{N}$ (since true in all models of PA).

Now suppose that $\operatorname{Pr}(\overline{\ulcorner\phi\urcorner})$ is true in $\mathbb{N}$.
Now $\operatorname{Pr}(\overline{\Gamma \phi})$ is an existential statement saying that there is an $n$ such that $n$ is the Gödel number of a proof whose last line is $\phi$. Since it is true in $\mathbb{N}$, there must be a natural number $n$ about which the formula $\operatorname{proof}(\overline{\ulcorner\phi}, \bar{n})$ is true. Then $n$ is indeed the Gödel number of a proof in $S$ whose last line is $\phi$, and so that proof witnesses that $\phi$ is provable in $S$.

### 6.2. A limit on the power of proof

Theorem 6.2.1. (Weak form of the First Incompleteness Theorem) Suppose that $S$ is a provably definable set of sentences that is true in $\mathbb{N}$ and includes $P A$.

Then there exists a formula $G$ such that $G$ is true in $\mathbb{N}$, but is not provable from $S$.
Proof: Using the Diagonal Lemma, find a formula $G$ such that $G \leftrightarrow \neg \operatorname{Pr}_{S}(\overline{\ulcorner G\urcorner})$ is provable from PA.

Suppose that $G$ is provable from $S$. Then $G$ is true in $\mathbb{N}$, by assumption and by soundness. Also $\operatorname{Pr}_{S}(\overline{\ulcorner G})$ is true by Theorem 6.1.4. But then $G$ is false, contradiction.

So $G$ is not provable from $S$.
Now suppose that $G$ is false. Then $\operatorname{Pr}_{S}(\overline{\ulcorner G\urcorner})$ is true, so $G$ is provable from $S$ by Theorem 6.1.4. But $S$ is true in $\mathbb{N}$, so $G$ is true in $\mathbb{N}$ also by soundness, contradiction.

So $G$ is true in $\mathbb{N}$.

### 6.3. Grades of completeness

Definition 6.3.1. A set of axioms $S$ is $n$-inconsistent if and only if there exists a $\Sigma_{n}$ formula $\exists x \phi(x)$ such that $\vdash_{S} \exists x \phi(x)$, but for all $m, \vdash_{S} \neg \phi(\bar{n})$.
$S$ is $n$-consistent if and only if it is not $n$-inconsistent.
$S$ is $\omega$-consistent if and only if it is $n$-consistent for all $n$.
Definition 6.3.2. A set $S$ of statements is $\Sigma_{i}$-complete if and only if all true $\Sigma_{i}$ sentences are provable from $S$.

We will say it is $\Sigma_{i}$-sound if and only if all $\Sigma_{i}$-sentences provable from $S$ are true.
Definition 6.3.3. The axiom scheme $Q$ is the following list of axioms:
$\forall v_{1} \forall v_{2} v_{1}{ }^{+}=v_{2}{ }^{+} \rightarrow v_{1}=v_{2}$.
$\forall v_{1} \neg v_{1}{ }^{+}=\overline{0}$.
$\forall v_{1} v_{1}+\overline{0}=v_{1}$.
$\forall v_{1} \forall v_{2} v_{1}+v_{2}^{+}=\left(v_{1}+v_{2}\right)^{+}$.
$\forall v_{1} v_{1} \cdot \overline{0}=\overline{0}$.
$\forall v_{1} \forall v_{2} v_{1} \cdot v_{2}{ }^{+}=v_{1} \cdot v_{2}+v_{1}$.
$\forall v_{1} v_{1} \leq \overline{0} \leftrightarrow v_{1}=\overline{0}$.
$\forall v_{1} \forall v_{2} v_{1} \leq v_{2}{ }^{+} \leftrightarrow\left(v_{1} \leq v_{2} \vee v_{1}=v_{2}^{+}\right)$.
$\forall v_{1} \forall v_{2} v_{1} \leq v_{2} \vee v_{2} \leq v_{1}$.
This has no induction.
Definition 6.3.4. The following list of axioms is known as $R$.
All sentences $\bar{m}+\bar{n}=\bar{k}$, for which $m+n=k$.
All sentences $\bar{m} . \bar{n}=\bar{k}$, for which $m . n=k$.
All sentences $\bar{m} \neq \bar{n}$, where $m \neq n$.
All sentences $\forall v_{1} v_{1} \leq \bar{n} \leftrightarrow\left(v_{1}=\overline{0} \vee \cdots \vee x=\bar{n}\right)$.
All sentences $\forall v_{1} v_{1} \leq \bar{n} \vee \bar{n} \leq v_{1}$.
Proposition 6.3.5. $Q$ extends $R$.
THEOREM 6.3.6. $R$ is $\Sigma_{0}$-complete.
Proof: The second-to-last schema gives a method of eliminating bounded quantifiers.

The other axioms allow us to compute the diagrams of + , . and $\leq$.
Corollary 6.3.7. $Q$ and $P A$ are $\Sigma_{0}$-complete.
Theorem 6.3.8. Any system $S$ that is $\Sigma_{0}$-complete is also $\Sigma_{1}$-complete.
Proof: Suppose that $\exists v_{1} F\left(v_{1}\right)$ is true. Then $F(\bar{n})$ is true for some $n$. Then $S \vdash F(\bar{n})$ by $\Sigma_{0}$-completeness. So $S \vdash \exists v_{1} F\left(v_{1}\right)$ as required.

Corollary 6.3.9. $R$, $Q$, and PA are $\Sigma_{1}$-complete.
Presburger arithmetic is PA with all mention of multiplication erased.
Definition 6.3.10. The following list of statements, in the sublanguage $\mathscr{L}_{P}$ of $\mathscr{L}$ containing no uses of the multiplication symbol $f^{\prime}$, is known as Presburger arithmetic:

1. $\neg \forall v_{i} v_{i}^{+}=\overline{0} ; \forall v_{i} \forall v_{j}\left(v_{i}^{+}=v_{j}^{+} \rightarrow v_{i}=v_{j}\right)$.
( $n \mapsto n^{+}$is an injection from $\mathbb{N} \leftrightarrow \mathbb{N} \backslash\{0\}$ ).
2. $\forall v_{i} v_{i}+\overline{0}=v_{i}$.
3. $\forall v_{i} \forall v_{j} v_{i}+v_{j}^{+}=(m+n)^{+}$.
4. $\forall v_{i} \overline{0} \leq v_{i} ; \forall v_{i} \forall v_{j}\left(v_{i} \leq v_{j} \leftrightarrow\left(v_{i}=v_{j} \vee v_{i}{ }^{+} \leq v_{j}\right)\right) ; \forall v_{i} v_{i} \leq v_{i} ; \forall v_{i} \forall v_{j}\left(v_{i} \leq\right.$ $\left.v_{j} \vee v_{j} \leq v_{i}\right) ; \forall v_{i} \forall v_{j} \forall v_{k}\left(\left(v_{i} \leq v_{j} \wedge v_{j} \leq v_{k}\right) \rightarrow\left(v_{i} \leq v_{k}\right)\right) ; \forall v_{i} \forall v_{j}\left(\left(v_{i} \leq v_{j} \wedge v_{j} \leq v_{i}\right) \rightarrow\right.$ $v_{i}=v_{j}$.
( $\leq$ is a total order, with initial element 0 , and $n^{+}$is the immediate successor of $n$ ).
5. (Induction Schema): For any formula $\phi\left(v_{1}\right)$ of $\mathscr{L}_{P}$, the following is an axiom: if $\phi(0)$, and if for all $n, \phi(n)$ implies $\phi\left(n^{+}\right)$, then $\forall n \phi(n)$.

Formally:

$$
\left(\left(\phi(\overline{0}) \wedge\left(\forall v_{1} \phi\left(v_{1}\right) \rightarrow \phi\left(v_{1}^{+}\right)\right)\right) \rightarrow \forall v_{1} \phi\left(v_{1}\right)\right) .
$$

The following theorem is not examinable for part C or OMMS.
Theorem 6.3.11. Presburger arithmetic is consistent and complete, and the set of consequences of it is decidable.

Proof: Rather long, very ingenious, and involving quantifier elimination and modular arithmetic.

So multiplication is not definable in $\mathscr{L}_{P}$.

### 6.4. The first incompleteness theorem

Theorem 6.4.1. (First Incompleteness Theorem) There exists a $\Pi_{1}$-sentence $G$ such that if PA is consistent, then PA $\vdash G$, and if in addition PA is 1 -consistent, then PA $\vdash \neg G$.

Proof: Apply the Diagonal Lemma to the statement $\neg \operatorname{Pr}_{\mathrm{PA}}\left(\overline{\left\ulcorner v_{1}\right\urcorner}\right)$, to obtain a formula $G$ such that $G$ is provably equivalent to $\neg \operatorname{Pr}_{\mathrm{PA}}(\overline{\ulcorner G\urcorner})$.

Suppose that $\mathrm{PA} \vdash G$.
Then PA $\vdash \operatorname{Pr}_{\mathrm{PA}}(\overline{\ulcorner G\urcorner})$, by Theorem 6.1.1.
So since PA $\vdash G$, PA $\vdash \neg \operatorname{Pr}_{\mathrm{PA}}(\overline{\ulcorner G\urcorner})$.
Thus PA is inconsistent, giving a contradiction.
Now suppose that PA $\vdash \neg G$, and that PA is 1 -consistent.
Then PA $\vdash \operatorname{Pr}_{\mathrm{PA}}(\overline{\ulcorner G\urcorner})$, because $G$ is provably equivalent to $\neg \operatorname{Pr}_{\mathrm{PA}}(\overline{\ulcorner G\urcorner})$.
Now $\operatorname{Pr}_{\mathrm{PA}}(\overline{\ulcorner G\urcorner})$ is the same thing as $\exists x \operatorname{proof}_{\mathrm{PA}}(\overline{\ulcorner G\urcorner}, x)$, and $\operatorname{proof}_{\mathrm{PA}}(\overline{\ulcorner G\urcorner}, x)$ is $\Sigma_{1}$.

Write proof ${ }_{\mathrm{PA}}(\overline{\ulcorner G\urcorner}, x)$ as $\exists y \phi(x, y)$, where $\phi(x, y)$ is $\Sigma_{0}$.
Then $\exists x \exists y \phi(x, y)$ may be rewritten $\exists z \exists x \leq z \exists y \leq z \phi(x, y)$, which is $\Sigma_{1}$ in the strict sense.

Now PA $\vdash \exists z \exists x \leq z \exists y \leq z \phi(x, y)$, so because PA is 1-consistent, there must exist $n$ such that PA $\vdash \neg \exists x \leq \bar{n} \exists y \leq \bar{n} \phi(x, y)$.

But PA is $\Sigma_{0}$-complete by Lemma 5.3.6., so PA $\vdash \exists x \leq \bar{n} \exists y \leq \bar{n} \phi(x, y)$.
So this statement is true in $\mathbb{N}$. Let $m$ be such that $\mathbb{N} \vDash \exists y \leq \bar{n} \phi(\bar{m}, y)$.
Then $\mathbb{N} \vDash \operatorname{proof}_{\mathrm{PA}}(\overline{\ulcorner G\urcorner}, \bar{m})$.
Hence $m$ is the Gödel number of a proof of $G$ in PA.
So we can read off a proof of $G$ in PA from $m$, and see that PA $\vdash G$.
Hence PA is inconsistent, giving a contradiction.
We can generalise this to other axiom systems which imply PA, except that we weaken the conclusion so that $G$ becomes $\Pi_{n}$ where $n \geq 1$ and the given axiom system is $\Delta_{n}$.
Corollary 6.4.2. Assume $\mathbb{N}$ is a model of PA. Then $G$ is true in $\mathbb{N}$ and not provable.
Proof: If $\mathbb{N}$ is a model of PA, then PA is consistent and 1-consistent.
Hence PA proves neither $G$ nor $\neg G$.
Since PA does not prove $G$, there is no natural number coding a proof of $G$, so then $\neg \operatorname{Pr}_{\mathrm{PA}}(\bar{G})$ is true in $\mathbb{N}$, so $G$ is true.

Theorem 6.4.3. (Rosser's Theorem) Let $S$ be any provably definable consistent set of sentences including PA. Then there is a sentence $G$ such that $S$ neither proves nor disproves $G$.
Proof: Let $H(x)$ be the statement $\exists y\left(\operatorname{proof}_{S}(\overline{\ulcorner\neg\urcorner \curvearrowright} x, y) \wedge \forall z \leq y \neg \operatorname{proof}_{S}(x, z)\right)$.
(Informally, $H(\overline{\ulcorner\phi\urcorner})$ says "there is a $y$ coding a refutation of $\phi$, and no $z \leq y$ codes a proof of $\phi^{\prime \prime}$.)

Using the Diagonal Lemma, let $G$ be such that $G \leftrightarrow H(\overline{\ulcorner G\urcorner})$ is provable from PA.
We argue that $S$ neither proves nor refutes $G$.
Suppose first that $S \vdash G$.
Then there is a proof of $G$ from $S$. Let $n$ be its Gödel number.
Then PA $\vdash \operatorname{proof}_{S}(\overline{\ulcorner G\urcorner}, \bar{n})$, and so $S \vdash \operatorname{proof}_{S}(\overline{\ulcorner G\urcorner}, \bar{n})$.
Now $S$ is consistent, so given that $S \vdash G$, then it is not the case that $S \vdash \neg G$; and so no disproof of $G$ exists.

So no natural number $m$ is the Gödel number of a proof from $S$ of $\neg G$; in particular no natural number $m<n$ is the Gödel number of a proof from $S$ of $\neg G$.

So if $m<n$, PA $\vdash \neg \operatorname{proof}_{S}(\overline{\ulcorner\neg G\urcorner}, \bar{m})$, so that PA $\vdash \forall m<\bar{n} \neg \operatorname{proof}_{S}(\overline{\ulcorner\neg G\urcorner}, \bar{m})$.
Now $n$ is the Gödel number of a proof of $G$ from $S$, so PA $\vdash \forall m \geq n \exists x \leq$ $m \operatorname{proof}_{S}(\overline{\ulcorner G\urcorner}, x)$ (the value of $x$ that witnesses this is of course $n$ itself).

Putting these two sentences together, PA $\vdash \forall y \neg\left(\operatorname{proof}_{S}(\overline{\ulcorner\neg G\urcorner}, y) \wedge \forall z \leq y \neg \operatorname{proof}_{S}(\overline{\ulcorner G\urcorner}, z)\right)$.
That is, PA $\vdash \neg H(\overline{\ulcorner G\urcorner})$. Hence $S \vdash \neg H(\overline{\ulcorner G\urcorner})$.
But $S \vdash G$, so $S \vdash H(\overline{\ulcorner G\urcorner), ~ g i v i n g ~ a ~ c o n t r a d i c t i o n . ~}$
Now suppose that $S \vdash \neg G$.
Then there is a proof of $\neg G$ from $S$. Let $n$ be the Gödel number of that proof.
Since $S$ is consistent, it is not possible that $S \vdash G$. So there is no proof of $G$ from $S$. So for all $m \leq n, m$ is not the Gödel number of a proof of $G$ from $S$.

Hence PA $\vdash\left(\operatorname{proof}(\overline{\ulcorner\neg G\urcorner}, \bar{n}) \wedge \forall m \leq n \neg \operatorname{proof}_{S}(G, m)\right)$.
So $S$ proves the same thing.
Hence $S \vdash H(\overline{\ulcorner G\urcorner)}$. From this it follows that $S \vdash G$, giving a contradiction.

### 6.5. The Second Incompleteness Theorem and Löb's Theorem

Theorem 6.5.1. (Second Incompleteness Theorem) If $S$ is a provably definable set of sentences including PA, and if a sentence $G$ has the property that $S \vdash G \leftrightarrow \neg \operatorname{Pr}_{S}(\overline{\ulcorner G\urcorner})$, then $S \vdash \neg \operatorname{Pr}_{S}(\overline{\ulcorner X\urcorner}) \rightarrow \neg \operatorname{Pr}_{S}(\overline{\ulcorner G\urcorner})$.
Proof: $\quad(G \rightarrow(\neg G \rightarrow X))$ is a tautology and so a theorem of $S$.
By hypothesis, $S \vdash\left(\operatorname{Pr}_{S}(\overline{\ulcorner G}) \rightarrow \neg G\right)$.
Hence $S \vdash\left(G \rightarrow\left(\operatorname{Pr}_{S}(\overline{\ulcorner G\urcorner}) \rightarrow X\right)\right)$.
From Theorem 6.1.1, and the assumption that $S$ extends PA, it follows that $S \vdash$ $\operatorname{Pr}_{S}\left(\overline{\left\ulcorner\left(G \rightarrow\left(\operatorname{Pr}_{S}(\overline{\ulcorner G\urcorner}) \rightarrow X\right)\right)\right.}\right)$.

From Theorem 6.1.2, we have $S \vdash\left(\operatorname{Pr}_{S}\left(\overline{\left\ulcorner\left(G \rightarrow\left(\operatorname{Pr}_{S}(\overline{\ulcorner G\urcorner}) \rightarrow X\right)\right)\right\urcorner}\right) \rightarrow\left(\operatorname{Pr}_{S}(\overline{\ulcorner G\urcorner}) \rightarrow\right.\right.$ $\left.\operatorname{Pr}_{S}\left(\overline{\left.\left\ulcorner\left(\operatorname{Pr}_{S}(\overline{\ulcorner G\urcorner}) \rightarrow X\right)\right\urcorner\right)}\right)\right)$.

Hence $S \vdash\left(\operatorname{Pr}_{S}(\overline{\ulcorner G\urcorner}) \rightarrow \operatorname{Pr}_{S}\left(\overline{\left\ulcorner\left(\operatorname{Pr}_{S}(\overline{\ulcorner G\urcorner}) \rightarrow X\right)\right\urcorner}\right)\right)$.
Also from Theorem 6.1.2, we have $S \vdash\left(\operatorname{Pr}_{S}\left(\left\ulcorner\left(\operatorname{Pr}_{S}(\overline{\ulcorner G}) \rightarrow X\right)\right\urcorner\right) \rightarrow\left(\operatorname{Pr}_{S}\left(\overline{\left.\left.\operatorname{Pr}_{S}(\overline{\ulcorner G})\right\urcorner\right)} \rightarrow\right.\right.\right.$ $\left.\operatorname{Pr}_{S}(\overline{\ulcorner X\urcorner})\right)$ ).

Thus $S \vdash\left(\operatorname{Pr}_{S}(\overline{\ulcorner G\urcorner}) \rightarrow\left(\operatorname{Pr}_{S}\left(\overline{\left\ulcorner\operatorname{Pr}_{S}(\overline{\ulcorner G\urcorner})\right\urcorner}\right) \rightarrow \operatorname{Pr}_{S}(\overline{\ulcorner X\urcorner})\right)\right)$.
Now by Theorem 6.1.3, we have that $S \vdash\left(\operatorname{Pr}_{S}(\overline{\ulcorner G\urcorner}) \rightarrow \operatorname{Pr}_{S}\left(\overline{\left\ulcorner\operatorname{Pr}_{S}(\overline{\ulcorner G\urcorner})\right\urcorner}\right)\right)$.
Thus $S \vdash\left(\operatorname{Pr}_{S}(\overline{\ulcorner G\urcorner}) \rightarrow \operatorname{Pr}_{S}(\overline{\ulcorner X\urcorner})\right)$.
Hence $S \vdash\left(\neg \operatorname{Pr}_{S}(\overline{\ulcorner X\urcorner}) \rightarrow \neg \operatorname{Pr}_{S}(\overline{\ulcorner G\urcorner})\right)$, as required.
Corollary 6.5.2. If $S$ is a provably definable set of sentences including PA, and if a sentence $G$ has the property that $S \vdash G \leftrightarrow \neg \operatorname{Pr}_{S}(\overline{\ulcorner G\urcorner}), X$ is a sentence, and $S$ is consistent, then $S \nvdash \neg \operatorname{Pr}(\overline{\ulcorner X\urcorner})$.
Proof: If $G$ exists, and $S \vdash \neg \operatorname{Pr}(\overline{\ulcorner X\urcorner})$, then $S \vdash \neg \operatorname{Pr}(\overline{\ulcorner G\urcorner})$, so $S \vdash G$. But then $S \vdash \operatorname{Pr}(\overline{\ulcorner G})$. So $S$ is inconsistent.

Definition 6.5.3. Suppose that $S$ is a definable set of sentences. We define $\mathrm{Con}_{S}$ to be the formula $\neg \operatorname{Pr}_{S}(\overline{\ulcorner\neg \overline{0}=\overline{0}\urcorner})$. We read this as " $S$ is consistent".
Corollary 6.5.4. If $S$ is a provably definable set of sentences including $P A$, and $S$ is consistent, then it is not the case that $S \vdash \mathrm{Con}_{S}$.

Proof: In fact, $S$ does not prove the statement $\neg \operatorname{Pr}_{S}(\overline{\ulcorner X\urcorner})$ for any formula $X$.
Theorem 6.5.5. (Löb's Theorem) Suppose that $S$ is a provably definable set of sentences extending $P A$. Then from $S \vdash\left(\operatorname{Pr}_{S}(\overline{\ulcorner\phi\urcorner}) \rightarrow \phi\right)$ we can deduce $S \vdash \phi$.
Proof: Let $L$ be diagonal for $\operatorname{Pr}_{S}(\cdot) \rightarrow \phi$, ie $S \vdash\left(L \leftrightarrow\left(\operatorname{Pr}_{S}(\overline{\ulcorner L\urcorner}) \rightarrow \phi\right)\right)$.
Then by Theorem 6.1.1, $S \vdash \operatorname{Pr}_{S}\left(\overline{\left.\left\ulcorner L \rightarrow\left(\operatorname{Pr}_{S}(\overline{(\bar{~})}) \rightarrow \phi\right)\right\urcorner\right)}\right.$.
By Theorem 6.1.2, $S \vdash \operatorname{Pr}_{S}(\overline{\ulcorner L\urcorner}) \rightarrow \operatorname{Pr}_{S}\left(\operatorname{Pr}_{S}(\overline{\ulcorner L\urcorner}) \rightarrow \phi\right)$.
By Theorem 6.1.2, $S \vdash \operatorname{Pr}_{S}\left(\overline{\left\ulcorner\operatorname{Pr}_{S}(\overline{\ulcorner L\urcorner})\right\urcorner}\right) \rightarrow\left(\operatorname{Pr}_{S}\left(\overline{\left\ulcorner\operatorname{Pr}_{S}(\overline{\ulcorner L})\right\urcorner}\right) \rightarrow \operatorname{Pr}_{S}(\overline{\ulcorner\phi\urcorner})\right.$, so $S \vdash$ $\operatorname{Pr}_{S}(\overline{\ulcorner L\urcorner}) \rightarrow\left(\operatorname{Pr}_{S}\left(\overline{\left\ulcorner\operatorname{Pr}_{S}(\overline{\ulcorner L\urcorner})\right\urcorner}\right) \rightarrow \operatorname{Pr}_{S}(\overline{\ulcorner\phi\urcorner})\right)$ by HS, so $S \vdash\left(\left(\operatorname{Pr}_{S}(\overline{\ulcorner L\urcorner}) \rightarrow \operatorname{Pr}_{S}\left(\overline{\left\ulcorner\operatorname{Pr}_{S}(\overline{\ulcorner L\urcorner})\right\urcorner}\right)\right) \rightarrow\right.$
$\left.\left(\operatorname{Pr}_{S}(\overline{\ulcorner L\urcorner}) \rightarrow \operatorname{Pr}_{S}(\overline{\ulcorner\phi\urcorner})\right)\right)$ by (A2), so $S \vdash\left(\operatorname{Pr}_{S}(\overline{\ulcorner L\urcorner}) \rightarrow \operatorname{Pr}_{S}(\overline{\ulcorner\phi\urcorner})\right)$ by Theorem 6.1.3 and MP.

Using HS, $S \vdash \operatorname{Pr}_{S}(\overline{\ulcorner L\urcorner}) \rightarrow \phi$.
But this is equivalent to $L$, so $S \vdash L$.
By Theorem 6.1.1, $S \vdash \operatorname{Pr}_{S}(\overline{\ulcorner L\urcorner})$.
Now by MP, $S \vdash \phi$ as required.

### 6.6. A stronger version of $\Sigma_{1}$-completeness

We proved earlier that if $\phi$ is $\Sigma_{1}$ and true, then it is provable.
In this section we strengthen this result.
THEOREM 6.6.1. If $\phi$ is a $\Sigma_{1}$ sentence, then $\mathrm{PA} \vdash\left(\phi \rightarrow \operatorname{Pr}_{\mathrm{PA}}(\overline{\ulcorner\phi\urcorner})\right)$.
Sketch proof: We show that if $\mathfrak{N}$ is a model of PA, then $\mathfrak{N} \vDash \phi \rightarrow \operatorname{Pr}_{\mathrm{PA}}(\overline{\ulcorner\phi\urcorner})$.
So, assume that $\mathfrak{N} \vDash$ PA.
Then we carry out, in $\mathfrak{N}$, the construction of a partial function $F$ such that, if $\phi$ is a $\Sigma_{0}$ sentence, then

$$
\mathfrak{N} \vDash \phi \rightarrow \underset{\mathrm{PA}}{\operatorname{proof}}\left(\overline{\ulcorner\phi\urcorner}, F(\overline{\ulcorner\phi\urcorner}) \wedge \overline{\left\ulcorner\phi^{\urcorner}\right.} \overline{\ulcorner \#\urcorner}\right),
$$

and

$$
\mathfrak{N} \vDash \neg \phi \rightarrow \underset{\mathrm{PA}}{\operatorname{proof}}\left(\overline{\ulcorner\neg \phi\urcorner}, F(\overline{\ulcorner\phi\urcorner}) \wedge \overline{\left\ulcorner\neg \phi^{\urcorner}\right.} \overline{\ulcorner \#\urcorner}\right) .
$$

We do this by a messy induction on $\phi$, of which the messiest part is when $\phi$ is atomic or negated atomic.

The following special cases can be done algorithmically using induction:

1. $\bar{n}=\bar{n}$ is a logical axiom.
2. $\neg \bar{m}=\bar{n}$ where $m \neq n$.
3. $\bar{m}+\bar{n}=\overline{m+n}$ and $\bar{m} \cdot \bar{n}=\overline{m \cdot n}$.

Bounded quantifiers can be coped with as follows.
If $\phi=\forall m \leq n \psi(\bar{m})$, then the following procedure can be expressed in $\mathscr{L}$ : for each $m \leq n$, write down a proof of $\psi(\bar{m})$, deduce $\bigvee_{m \leq n} \psi(\bar{m})$, and then by induction on $n$ deduce $\forall m \leq n \psi(\bar{m})$; the result is a proof of $\phi$.

We treat bounded existential quantifiers in a similar way.
Now $\bar{m} \leq \bar{n}$ is provably equivalent to $\exists k \leq n \bar{m}+k=\bar{n}$.
Now any $\Sigma_{0}$ formula is provably equivalent, by standard proofs that can be expressed in $\mathscr{L}$, to a disjunction of conjunctions of statements of the above forms.

So, for any $\Sigma_{0}$ formula $\psi$, we have

$$
\mathfrak{N} \vDash \psi \rightarrow \underset{\mathrm{PA}}{\operatorname{proof}}\left(\overline{\ulcorner\psi\urcorner}, F(\overline{\ulcorner\phi\urcorner}) \wedge \overline{\left\ulcorner\psi^{\vee}\right.}{ }^{\wedge} \overline{\ulcorner } \#^{\urcorner}\right),
$$

and

Now suppose $\phi$ is a $\Sigma_{1}$ formula $\exists x \psi(x)$.

Then

$$
\mathfrak{N} \vDash \forall x\left(\psi(x) \rightarrow \underset{\mathrm{PA}}{\operatorname{proof}}\left(\overline{\ulcorner\psi(x)\urcorner}, F(\overline{\ulcorner\psi(x)\urcorner}) \wedge \overline{\ulcorner\psi(x))^{\wedge}} \overline{\ulcorner \#\urcorner}\right)\right),
$$

so

$$
\mathfrak{N} \vDash \forall x\left(\psi(x) \rightarrow \operatorname{Pr}_{\mathrm{PA}}(\overline{\ulcorner\psi(x)\urcorner})\right),
$$

so

$$
\mathfrak{N} \vDash \exists x(\psi(x) \rightarrow \exists x \underset{\mathrm{PA}}{\operatorname{Pr}}(\overline{\ulcorner\psi(x)\urcorner}),
$$

so

$$
\mathfrak{N} \vDash \exists x\left(\psi(x) \rightarrow \operatorname{Pr}_{\mathrm{PA}}(\overline{\ulcorner\exists x \psi(x)\urcorner)}),\right.
$$

as required.
THEOREM 6.6.2. If $\phi(x)$ is $\Sigma_{1}$, then the statement $\forall x\left(\phi(x) \rightarrow \operatorname{Pr}_{\mathrm{PA}}(\overline{\ulcorner\phi(x)})\right)$ is a theorem of PA.

Sketch proof: This is proved by the same techniques as the previous theorem.

## 7. Strengthenings of PA

Given that PA is incomplete, we look around for reasonable strengthenings of it. We could use $\mathrm{PA} \cup \mathrm{Con}_{\mathrm{PA}}, \mathrm{PA} \cup \mathrm{Con}_{\mathrm{PA}} \cup \mathrm{Con}_{\mathrm{PA} \cup \mathrm{Con}_{\mathrm{PA}}}$, etc. The next section provides a more systematic possible approach.

### 7.1. The $\omega$-rule

## Definition 7.1.1. Suppose that $S$ is a set of formulae of $\mathscr{L}$.

We define $S^{\omega}$ to be the logical system whose axioms are $S$ together with all logical axioms, and whose rules are MP, Gen, and the $\omega$-rule which allows one to deduce $\forall x \phi(x)$ from the entire set of assumptions $\{\phi(\bar{n}): n \in \mathbb{N}\}$.
$A$ proof in $S^{\omega}$ is a sequence $\left(\phi_{\alpha}: \alpha<\beta\right)$, where $\beta$ is an ordinal, such that each $\phi_{\alpha}$ is an element of $S$ or a logical axiom, or else is obtained from previous members of the sequence using a rule.
$\phi$ is a theorem of $S^{\omega}$, and we write $S^{\omega} \vdash \phi$, iff there is a proof in $S^{\alpha}$ of which $\phi$ is the last element.

We could, if we wished, insist that all proofs have length $<\omega_{1}$.
The $\omega$-rule looks reasonable-ish. However there is a big problem with it.
Theorem 7.1.2. $\quad R^{\omega}$ is complete.
Proof: We can prove by induction on the complexity of a formula $\phi$ that $R^{\omega} \vdash \phi$ or $R^{\omega} \vdash \neg \phi$.

The $\omega$-rule allows us to eliminate quantifiers.
The case where $\phi$ is $\Sigma_{0}$ is already done since $R$ is $\Sigma_{0}$-complete.
Now suppose that $\phi$ is $\Sigma_{n+1}$; say $\phi=\exists x \psi(x)$.
There are two cases. If there exists $n$ such that $R^{\omega} \vdash \psi(\bar{n})$, then it is certainly true that $R^{\omega} \vdash \exists x \psi(x)$, so $R^{\omega} \vdash \phi$. The alternative is (appealing to the inductive hypotheis) that for all $n, R^{\omega} \vdash \neg \psi(\bar{n})$. Then by the $\omega$-rule, $R^{\omega} \vdash \forall x \neg \psi(x)$, so $R^{\omega} \vdash \neg \phi$.

This argument of course also does the case when $\phi$ is $\Pi_{n+1}$.
Corollary 7.1.3. $\mathrm{PA}^{\omega}$ is complete.
Corollary 7.1.4. Assuming that $R^{\omega}$ and $\mathrm{PA}^{\omega}$ are sound with respect to truth in $\mathbb{N}$, then the set of theorems of $R^{\omega}$ or of $\mathrm{PA}^{\omega}$ is undefinable and so a fortiori not recursively enumerable.

Proof: Using Tarski's Theorem, and the statement that a set is recursively enumerable iff it is $\Sigma_{1}$-definable.

The upshot is that since, as human beings, we are limited to what is recursively enumerable, $R^{\omega}$ and $\mathrm{PA}^{\omega}$ are of no practical use.

In the next section we look at an adaptation of the $\omega$-rule which may be more useful.

### 7.2. The uniform reflection principle

The uniform reflection principle is an arithmetised version of the $\omega$-rule, and says "if $\phi(\bar{n})$ is provable for all $n$, then $\forall x \phi(x)$ is true" (which can be said in the language).
Definition 7.2.1. The uniform reflection principle URP is the set of axioms got by adding to PA all instances of the following, where $F\left(v_{1}\right)$ is a formula of $\mathscr{L}$ :

$$
\forall n \operatorname{Pr}_{\mathrm{PA}}\left(\overline{\left\ulcorner\forall v_{1}\left(v_{1}=\right\urcorner \wedge\ulcorner\bar{n}\urcorner \wedge\left\ulcorner\rightarrow F\left(v_{1}\right)\right)\right\urcorner}\right) \rightarrow \forall n F(n) .
$$

We write this as $\forall n \operatorname{Pr}_{\mathrm{PA}}(\overline{\ulcorner F[\overline{\tilde{n}]}\urcorner}) \rightarrow \forall n F(n)$, and refer to it as the reflection principle for $F$.

This is better-we have a definable set of axioms here - so less powerful. How powerful?
Theorem 7.2.2. Suppose that $G$ is a sentence such that $\mathrm{PA} \vdash G \leftrightarrow \neg \operatorname{Pr}_{\mathrm{PA}}(\overline{\ulcorner G\urcorner})$.
Then $\mathrm{PA} \vdash \forall n \operatorname{Pr}_{\mathrm{PA}}\left(\overline{\left\ulcorner\neg \operatorname{proof}_{\mathrm{PA}}(\overline{\ulcorner G\urcorner}, \dot{n})\right\urcorner}\right)$.
Proof: Recall that proof $\mathrm{PA}_{\mathrm{PA}}$ is $\Delta_{1}$.
Suppose that $\mathfrak{N}$ is a model of PA , and that $n \in \mathfrak{N}$.
Then either $\operatorname{proof}_{\mathrm{PA}}(\overline{\bar{G}}, n)$ is true in $\mathfrak{N}$, or $\neg \operatorname{proof}_{\mathrm{PA}}(\overline{\ulcorner G\urcorner}, n)$ is true.
If $\mathfrak{N} \vDash \neg \operatorname{proof}_{\mathrm{PA}}(\overline{\ulcorner G\urcorner}, n)$ is true, then because $\neg \operatorname{proof}_{\mathrm{PA}}(\overline{\ulcorner G\urcorner}, n)$ is $\Sigma_{1}$, then by Theorem 5.6.2., $\mathfrak{N} \vDash \forall x\left(\neg \operatorname{proof}_{P A}(\bar{G}, x) \rightarrow \operatorname{Pr}_{P A}\left(\neg \operatorname{proof}_{P A}(\overline{\ulcorner G\urcorner}, x)\right)\right)$, so we we deduce that $\mathfrak{N} \vDash \operatorname{Pr}_{\mathrm{PA}}\left(\overline{\neg \operatorname{proof}_{\mathrm{PA}}(\overline{\ulcorner G\urcorner}, \bar{n})}\right)$.

If on the other hand proof ${ }_{\mathrm{PA}}(\overline{\ulcorner G\urcorner}, n)$, then $\operatorname{Pr}_{\mathrm{PA}}(\overline{\ulcorner G\urcorner})$, and so $\operatorname{Pr}_{\mathrm{PA}}(\overline{\ulcorner X\urcorner})$ for all $X$ by the Second Incompleteness Theorem, and so $\operatorname{Pr}_{\mathrm{PA}}\left(\overline{\left\ulcorner\neg \operatorname{proof}_{\mathrm{PA}}(\overline{\ulcorner G\urcorner}, \bar{n})\right\urcorner}\right)$ in particular.

Corollary 7.2.3. URP $\vdash G$.
Proof: Using the previous theorem and URP, we have URP $\vdash \forall n \neg \operatorname{proof}_{\mathrm{PA}}(\overline{\ulcorner G\urcorner}, n)$, that is, URP $\vdash \neg \operatorname{Pr}(\overline{\Gamma G\urcorner})$, from which we deduce URP $\vdash G$.

So URP is stronger than PA. By how much?
Theorem 7.2.4. Writing $\mathrm{URP}_{\Pi_{1}}$ for the axiom system got by adding to PA only instances of the reflection principle for $\Pi_{1}$ formulae, $\mathrm{PA} \cup \mathrm{URP}_{\Pi_{1}}$ is equivalent to $\mathrm{PA} \cup\left\{\mathrm{Con}_{\mathrm{PA}}\right\}$.

Proof: Assume PA $\cup \mathrm{URP}_{\Pi_{1}}$. We set out to prove Con $_{\mathrm{PA}}$.
Recall that $\operatorname{Con}_{\mathrm{PA}}$ is $\neg \operatorname{Pr}_{\mathrm{PA}}(\overline{\ulcorner\neg \overline{0}=\overline{0}\urcorner})$, which is $\forall x \neg \operatorname{proof}_{\mathrm{PA}}(\overline{\ulcorner\neg \overline{0}=\overline{0}\urcorner}, x)$.
Recalling that proof PA is $\Delta_{1}$, express $\neg \operatorname{proof}_{\mathrm{PA}}(\overline{\ulcorner\neg \overline{0}=\overline{0}\urcorner}, x)$ as $\forall y \psi(x, y)$.
So, $\mathrm{Con}_{\mathrm{PA}}$ can be written as $\forall z \forall x \leq z \forall y \leq z \psi(x, y)$.
Now $\neg \overline{0}=\overline{0} \rightarrow \forall x \leq z \forall y \leq z \psi(x, y)$ is an instance of a tautology.
Thus, using the first two provability rules, $\operatorname{Pr}_{P A}(\overline{\ulcorner\neg \overline{0}=\overline{0}\urcorner}) \rightarrow \operatorname{Pr}_{P A}(\forall x \leq z \forall y \leq$ $z \psi(x, y))$ is provable.

It follows that if for some $z, \neg \operatorname{Pr}_{\mathrm{PA}}(\forall x \leq z \forall y \leq z \psi(x, y))$ is true in a particular model of PA , then so is $\neg \operatorname{Pr}(\overline{\ulcorner\neg \overline{0}=\overline{0}\urcorner})$; that is, $\mathrm{Con}_{\mathrm{PA}}$ is true, as desired.

If, on the other hand, $\forall z \operatorname{Pr}_{\mathrm{PA}}(\forall x \leq z \forall y \leq z \psi(x, y))$ holds in the model, then by $\mathrm{URP}_{\Pi_{1}}$, we have $\forall z \forall x \leq z \forall y \leq z \psi(x, y)$, and thus we again have Con $\mathrm{CA}_{\mathrm{PA}}$.

Now assume that $\mathrm{PA} \cup\left\{\mathrm{Con}_{\mathrm{PA}}\right\}$ is true in a particular structure $\mathfrak{N}$.
Suppose that $F(x)$ is $\Pi_{1}$, and that in $\mathfrak{N}, \forall x \operatorname{Pr}_{\mathrm{PA}}(\overline{\ulcorner F(x)\urcorner})$ is true.
Suppose that $\mathfrak{N} \vDash \operatorname{Pr}_{\mathrm{PA}}(\overline{\ulcorner\neg F(\bar{x})\urcorner})$.
Then using 5.1.1. and 5.1.3., and the fact that $(F(x) \rightarrow(\neg F(x) \rightarrow \neg \overline{0}=\overline{0}))$ is a tautology, we conclude that $\mathfrak{N} \vDash \operatorname{Pr}_{P A}(\overline{\ulcorner\neg \overline{0}=\overline{0}\urcorner})$, contradicting the assumption that Con $_{\text {PA }}$ is true in $\mathfrak{N}$.

Hence $\mathfrak{N} \vDash \forall x \neg \operatorname{Pr}_{\mathrm{PA}}(\overline{\ulcorner\neg F(\overline{\bar{x}})})$.
Now $\neg F(x)$ is provably $\Sigma_{1}$, so PA $\vdash \forall n\left(\neg F(n) \rightarrow \operatorname{Pr}_{\mathrm{PA}}(\overline{\ulcorner\neg F(\bar{n})})\right)$.
So we deduce that in $\mathfrak{N}, \forall n F(n)$ holds, as required.

## 8. Gödel-Löb logic

Here we abstract out some of the features of the logic of provability we've been deriving, finding that a surprisingly small part of it is sufficient to give us the Incompleteness Theorems.

### 8.1. Definitions and basic results

Definition 8.1.1. Gödel-Löb logic is a system of modal propositional logic.
The symbols are: a countably infinite number of propositional variables $p, q, r$ etc; a logical constant $\perp$, a binary connective $\rightarrow$, and a unary operator $\square$.

The formulae are: all propositional variable letters; the symbol $\perp$; and all strings $(\phi \rightarrow \psi)$ and $\square \phi$ where $\phi$ and $\psi$ are formulae.

The logical axioms are all propositional tautologies (with $\perp$ interpreted as a contradiction), together with all instances of $\square(\phi \rightarrow \psi) \rightarrow(\square \phi \rightarrow \square \psi)$, and $\square(\square \phi \rightarrow \phi) \rightarrow \square \phi$. The rules of inference are modus ponens and necessitation, by which we mean the rule "if $\vdash \phi$, then $\vdash \square \phi$ ".
$\square \phi$ is to be interpreted " $\phi$ is provable".
The following theorem (whose proof is not examinable) shows that the abstraction process is very successful.
Theorem 8.1.2. Suppose that $\phi$ is a formula of GL logic.
Then $\vdash \phi$ if and only if whenever $\psi \mapsto \psi^{*}$ is a map from formulae of GL logic to formulae of $\mathscr{L}$ having the properties that $\perp^{*}$ is a contradiction, that $(\psi \rightarrow \chi)^{*}=\left(\psi^{*} \rightarrow \chi^{*}\right)$, and that $(\square \psi)^{*}=\operatorname{Pr}_{\mathrm{PA}}\left(\overline{\left\ulcorner\psi^{*}\right\urcorner}\right)$, $\mathrm{PA} \vdash \phi^{*}$.

Proof: The forward direction is relatively easy. The reverse direction involves clever use of what is known as Kripke frames, which are not on the syllabus of this course (unfortunately).

The following feature of propositional logic carries over.
Proposition 8.1.3. (Substitution) Suppose that $\phi, \chi, \psi$ and $\theta$ are formulae of GödelLöb logic, and that $\theta^{\prime}$ is obtained from $\theta$ by replacing one or more subformulae of $\theta$ that are copies of $\chi$, by copies of $\psi$.

Then $\vdash\left((\phi \rightarrow(\chi \leftrightarrow \psi)) \rightarrow\left(\phi \rightarrow\left(\theta \leftrightarrow \theta^{\prime}\right)\right)\right)$.
Proof: Induction on the complexity of $\theta$.
Proposition 8.1.4. (Modalised substitution) Suppose that $X=X(p)$ is a formula in which $p$ only occurs within the scope of $\square$ operators, and let $X(q)$ be the result of replacing all instances of $p$ in $X$ by $q$.

Then $\vdash(\square(p \leftrightarrow q) \rightarrow(X(p) \leftrightarrow X(q))$.
Proof: Induction on the complexity of $X$.

### 8.2. The fixed-point theorem for GL logic

Fixed point theorem; more abstract proof of incompleteness.
Theorem 8.2.1. Fixed point theorem: if $A(p)$ is a formula in which $p$ only occurs in the scope of $a \square$, then there exists a formula $X$, in which $p$ does not occur and containing only letters from $A(\cdot)$, such that $X \leftrightarrow A(X)$ is provable.

Moreover, $X$ is unique in the sense that $\vdash((\square(p \leftrightarrow A(p)) \wedge \square(q \leftrightarrow A(q))) \rightarrow \square(p \leftrightarrow q))$.
Lemma 8.2.2. If $B(p)$ is a formula, then there exists a formula $X$, in which $p$ does not occur and containing only letters from $B(\cdot)$, such that $X \leftrightarrow \square B(X)$ is provable.

Proof: The appropriate $X$ is: $\square B(\top)$, where $\top$ is some tautology (such as $\perp \rightarrow \perp$ ).
For, $\square B(\top) \rightarrow(\top \leftrightarrow \square B(\top))$ is a tautology.
Thus, using substitution, so is $\square B(T) \rightarrow(\square B(T) \leftrightarrow \square B(\square B(T)))$.
So we get $\square B(\mathrm{~T}) \rightarrow \square B(\square B(\mathrm{~T}))$.
As for the other way round, given $\square B(\top) \rightarrow(\top \leftrightarrow \square B(T))$, we use substitution again to get $\square B(\top) \rightarrow(B(T) \leftrightarrow B(\square B(T)))$.

It follows by propositional logic that $B(\square B(\top)) \rightarrow(\square B(\top) \rightarrow B(\top))$.
By necessitation, $\square(B(\square B(\top)) \rightarrow(\square B(\top) \rightarrow B(\top)))$.
Using the first axiom and MP, $\square B(\square B(T)) \rightarrow \square(\square B(T) \rightarrow B(T))$.
The second axiom scheme gives us $\square(\square B(T) \rightarrow B(T)) \rightarrow \square B(T)$.
Now by propositional logic, $\square B(\square B(T)) \rightarrow \square B(\mathrm{~T})$ as required.
Lemma 8.2.3. Given a set of formulae $C_{i}\left(D\left(p_{1}, \ldots, p_{n}\right)\right)(i \leq n)$, there exist formulae $F_{i}$ for $i \leq n$ such that $\vdash\left(F_{i} \leftrightarrow \square C_{i}\left(D\left(F_{1}, \ldots, F_{n}\right)\right)\right)$.

Proof: We do induction on $n$.
The base case was done above. Suppose that any such family of equivalences of size $n$ can be solved, and suppose that we have a family of formulae $C_{i}\left(D\left(p_{1}, \ldots, p_{n+1}\right)\right)$ $(i \leq n+1)$.

Then we set $C_{n+1}$ aside for a moment. Let $q$ be some propositional letter we have not yet used. Using the inductive hypothesis, let $G_{i}(q)$ (for $i \leq n$ ) be formulae such that

$$
\vdash G_{i}(q) \leftrightarrow \square C_{i}\left(D\left(G_{1}(q), \ldots, G_{n}(q), q\right)\right)
$$

$(i \leq n)$.
Now use the preceding lemma to find $F_{n+1}$ such that

$$
\vdash F_{n+1} \leftrightarrow \square C_{n+1}\left(D\left(G_{1}\left(F_{n+1}\right), \ldots, G_{n}\left(F_{n+1}\right), F_{n+1}\right)\right)
$$

Now, for $i \leq n$, let $F_{i}=G_{i}\left(F_{n+1}\right)$.
Lemma 8.2.4. (Existence of the fixed point) If $A(p)$ is a formula in which $p$ only occurs in the scope of $a \square$, then there exists a formula $X$, in which $p$ does not occur and containing only letters from $A(\cdot)$, such that $X \leftrightarrow A(X)$ is provable.
Proof: Suppose that $A(p)$ has the form $D\left(\square C_{1}(p), \ldots, \square C_{n}(p)\right)$. Use the preceding lemma to find $F_{i}$ equivalent to $\square C_{i}\left(D\left(F_{1}, \ldots, F_{n}\right)\right)$ for $i \leq n$; then $D\left(F_{1}, \ldots, F_{n}\right)$ is equivalent to $D\left(\square C_{1}\left(D\left(F_{1}, \ldots, F_{n}\right)\right), \ldots, \square C_{n}\left(D\left(F_{1}, \ldots, F_{n}\right)\right)\right)$, that is, to $A\left(D\left(F_{1}, \ldots, F_{n}\right)\right)$, which is what we want.
Lemma 8.2.5. (Uniqueness of the fixed point) Suppose that $A(p)$ is a formula in which $p$ only occurs in the scope of $a \square$, and that $X$ is a formula in which $p$ does not occur and containing only letters from $A(\cdot)$, such that $X \leftrightarrow A(X)$ is provable.

Then $X$ is unique in the sense that $\vdash((\square(p \leftrightarrow A(p)) \wedge \square(q \leftrightarrow A(q))) \rightarrow \square(p \leftrightarrow q))$.
Proof: We prove, using modalised substitution, that $\vdash \square(p \leftrightarrow q) \rightarrow(A(p) \leftrightarrow A(q))$.
By propositional logic, $\vdash(((p \leftrightarrow A(p)) \wedge(q \leftrightarrow A(q))) \rightarrow(\square(p \leftrightarrow q) \rightarrow(p \leftrightarrow q)))$.
Doing stuff with $\square$, we get $\vdash((\square(p \leftrightarrow A(p)) \wedge \square(q \leftrightarrow A(q))) \rightarrow \square(\square(p \leftrightarrow q) \rightarrow(p \leftrightarrow$ $q))$ ).

Then, using an axiom, $\vdash(\square(p \leftrightarrow A(p)) \wedge \square(q \leftrightarrow A(q))) \rightarrow \square(p \leftrightarrow q)$.
As an example of silly things happen if $p$ is not boxed, let $A$ be the identity.

### 8.3. The incompleteness theorems in GL logic

Theorem 8.3.1. (GL version of the First Incompleteness Theorem). There exists a formula $G$ such that $\vdash(G \leftrightarrow \neg \square G)$.

Proof: Define $G$ to be a/the fixed point of $\neg \square p$; that is, $\vdash G \leftrightarrow \neg \square G$.
Theorem 8.3.2. (GL version of the Second Incompleteness Theorem). For any formulae $A$ and $B, \vdash \square \neg \square A \rightarrow \square B$.
Proof: Now $\vdash(\neg \square A \rightarrow(\square A \rightarrow A)$, so $\vdash(\square \neg \square A \rightarrow \square(\square A \rightarrow A)$ ), so $\vdash(\square \neg \square A \rightarrow$ $\square A)$. So since, by Theorem 8.1.2., $\vdash(\square A \rightarrow \square \square A), \vdash(\square \neg \square A \rightarrow \square \square A)$.

Now $(\neg \square A \rightarrow(\square A \rightarrow B)$ ) by propositional calculus.
Hence, using Necessitation, the scheme $(\square(\phi \rightarrow \psi) \rightarrow(\square \phi \rightarrow \square \psi)$ ), and MP,

$$
\vdash(\square \neg \square A \rightarrow(\square \square A \rightarrow \square B)) .
$$

Then using propositional calculus,

$$
\vdash(\square \neg \square A \rightarrow \square B)
$$

as required.
The formula $\square \neg \square A \rightarrow \square B$ expresses the idea that if anything is provably unprovable, then the system is inconsistent.

## 9. Constructing models of PA inside other models of PA

### 9.1. Revision of Henkin's proof of the Completeness Theorem

Recall how the now standard proof of the Completeness Theorem goes. Given a countable language $L$ of first-order predicate calculus, we close the language under the addition of constant symbols $c_{\phi}$ for formulae $\phi$, and add to PA (or whatever other theory we may be interested in) extra axioms ( $\exists v_{1} \phi \rightarrow \phi\left(c_{\phi}\right)$ ). We then extend our theory to a complete consistent set of sentences, and a new model for the theory is then constructed from the closed terms (sc. terms containing no variable letters), in such a way that if $\phi\left(\sigma_{1}, \ldots, \sigma_{n}\right)$ is a member of the complete consistent set, then $\phi\left(\sigma_{1}, \ldots, \sigma_{n}\right)$ is true in that model.

So, once we have a process for deciding which sentences are members of our complete consistent set, the construction of the model is routine.

We focus on this process of identifying members of the complete consistent set.
First, we add the constant symbols to our language $\mathscr{L}$. We can do this in any number of ways. The method in the following definition relies on the fact that the string $\overline{0}^{\prime}$ never occurs in formulae of $\mathscr{L}$.
Definition 9.1.1. We define a language $\mathscr{L}^{*}$ with the same alphabet as $\mathscr{L}$, with its set of terms and its set of formulae being the smallest sets which have the following properties.
(1) Every term of $\mathscr{L}$ is a term of $\mathscr{L}^{*}$, and every formula of $\mathscr{L}$ is a formula of $\mathscr{L}^{*}$.
(2) If $\phi$ is a formula of $\mathscr{L}^{*}$, then $\overline{0}^{\prime}(\phi)$ is a term of $\mathscr{L}^{*}$ (which we will write as $c_{\phi}$ ).
(3) If $\sigma$ and $\tau$ are terms of $\mathscr{L}^{*}$, then so are $\sigma^{+},(\sigma f \tau)$ and $\left(\sigma f^{\prime} \tau\right)$.
(4) If $\sigma$ and $\tau$ are terms of $\mathscr{L}^{*}$, then $\sigma=\tau$ and $\sigma \leq \tau$ are formulae of $\mathscr{L}^{*}$.
(5) If $\phi$ and $\psi$ are formulae of $\mathscr{L}^{*}$, then so are $\neg \phi,(\phi \rightarrow \psi)$, and $\forall v_{i} \phi$.

We now add witnesses to existential statements to any theory of $\mathscr{L}$.
Definition 9.1.2. If $T$ is any set of sentences of $\mathscr{L}$, then we define $T^{*}$ to be the result of adding to $T$ all formulae $\left(\exists v_{1} \phi\left(v_{1}\right) \rightarrow \phi\left[c_{\phi}\right]\right)$.
Theorem 9.1.3. If $T$ is $\Sigma_{n}$-definable for $n \geq 1$, then $T^{*}$ is also $\Sigma_{n}$-definable. Similarly if $T$ is $\Pi_{n}$-definable for $n \geq 1$, then $T^{*}$ is also $\Pi_{n}$-definable.

Proof: The set of Gödel numbers of the extra axioms in $T^{*}$ is $\Delta_{1}$-definable.
We now take a closer look at the process of deriving the complete consistent set.
Theorem 9.1.4. Suppose that $T$ has a $\Delta_{n}$-definable proof predicate $\operatorname{Pr}_{T}$. Then there is a $\Delta_{n}$-definable function $\mathfrak{H}_{T}(n)$ such that if $n$ is the Gödel number of a sentence $\phi$ of $\mathscr{L}^{*}$, then in a model $\mathfrak{N}$ of PA, $\mathfrak{H}_{T}(\phi)=1$ if, defining $\theta_{n}$ to be the formula

$$
\theta_{n}=\bigwedge\left\{\psi:\ulcorner\psi\urcorner<n \wedge \mathfrak{H}_{T}(\ulcorner\psi\urcorner)=1\right\} \wedge \bigwedge\left\{\neg \psi:\ulcorner\psi\urcorner<n \wedge \mathfrak{H}_{T}(\ulcorner\psi\urcorner)=0\right\},
$$

$\operatorname{Pr}_{T}\left(\overline{\left\ulcorner\left(\theta_{n} \rightarrow \phi\right)\right.}\right)$ is true, and $\mathfrak{H}_{T}(n)=0$ otherwise.
We describe $\mathfrak{H}_{T}$ as successful if there exists $n$ such that $\mathfrak{H}_{T}(n)=0$.
Note that $\mathfrak{H}_{T}$ is successful in a model $\mathfrak{N}$ of PA if and only if $\mathfrak{N} \vDash \operatorname{Con}_{T}$.
Proof: To see that $\mathfrak{H}_{T}$ is $\Delta_{n}$-definable, note that the definition of $\mathfrak{H}_{T}$ is a definition by recursion using a $\Delta_{n}$-formula.

If $\mathfrak{H}_{T}$ is successful in a model $\mathfrak{N}$, then we think of $\mathfrak{H}_{T}$ as describing a model of $T$ inside $\mathfrak{N}$. It is certainly the case that from a successful function $\mathfrak{H}_{T}$, we can construct a model of $T$.

### 9.2. Comparing a model and a model inside that model

When we start to talk about models of arithmetic sitting inside models of arithmetic, questions about language and metalanguage, and problems posed by non-standard elements coding formulae and proofs, become complicated. For some results in this section, we restrict our attention to models of arithmetic sitting inside $\mathbb{N}$.
Theorem 9.2.1. If $\mathfrak{N}$ is a model of PA defined in $\mathbb{N}$ by a formula $\mathfrak{H}_{T}$, where $T$ extends $P A$, then $\mathfrak{N}$ is not elementarily equivalent to $\mathbb{N}$ (that is, there is a sentence which is true in $\mathfrak{N}$ and false in $\mathbb{N}$ ).

Proof: This follows from Tarski's Theorem. If $\mathfrak{N}$ and $\mathbb{N}$ were elementarily equivalent, then $\mathfrak{H}_{T}$ would define truth in $\mathbb{N}$, which is impossible.

This theorem can be extended, with extreme caution, to other models of PA.
Theorem 9.2.2. If $\phi$ is a sentence of $\mathscr{L}$, and $\mathfrak{N}$ is a model of $P A$, then there is a model $\mathfrak{N}^{\prime}$ of PA inside $\mathfrak{N}$ satisfying $\phi$ if and only if $\mathfrak{N} \vDash \neg \operatorname{Pr}_{\mathrm{PA}}(\overline{\ulcorner\neg \phi\urcorner})$, and every model $\mathfrak{N}^{\prime}$ of PA inside $\mathfrak{N}$ satisfies $\phi$ if and only if $\mathfrak{N} \vDash \operatorname{Pr}_{P A}(\overline{\ulcorner\phi\urcorner})$.

Restricting our attention to $\mathfrak{H}_{\text {PA }}$, we have the following.
Theorem 9.2.3. There is a $\Delta_{2}$-sentence $K$ such that if $\mathfrak{N}$ is a model of $P A$ and $\mathfrak{N}^{\prime}$ is constructed inside $\mathfrak{N}^{\prime}$ using $\mathfrak{H}_{\text {PA }}$, then $K$ is true in $\mathfrak{N}$ if and only if it is false in $\mathfrak{N}^{\prime}$.

Proof: Use the Diagonal Lemma to find $K$ such that PA $\vdash\left(K \leftrightarrow\left(\neg \mathfrak{H}_{\mathrm{PA}}(\overline{\ulcorner K\urcorner})\right)\right)=\overline{1}$.
We can regard $K$ as being $\Delta_{2}$ because $\mathfrak{H}_{\text {PA }}$ is.
Corollary 9.2.4. Any chain $\mathfrak{N}_{i}$ of models of PA, where $\mathfrak{N}_{i+1}$ is constructed inside $\mathfrak{N}_{i}$ using $\mathfrak{H}_{\text {PA }}$, is finite.

Proof: We order functions from $\mathbb{N}$ to $\{0,1\}$ lexicographically, that is, so that $f \leq g$ iff either $f=g$, or there exists $n$ such that for all $m<n, f(m)=g(m)$, and $f(n)<g(n)$.

We define $f_{i}$ so that for all $n \in \mathbb{N}, f_{i}(n)=1$ if and only if $n$ is the Gödel number of a sentence $\phi$ such that $\mathfrak{N}_{i} \vDash \phi$.

Let $k=\overline{\ulcorner K\urcorner}$. Then for all $i, f_{i}(k) \neq f_{i+1}(k)$.
We now note that if $i>1$, then $f_{i} \leq f_{i+1}$. For, suppose that $n$ is least such that $f_{i}(n) \neq f_{i+1}(n)$. Then in one of $\mathfrak{N}_{i-1}$ and $\mathfrak{N}_{i}$ but not the other, $\operatorname{Pr}_{\mathrm{PA}}\left(\overline{\left(\overline{\left(\theta_{n} \rightarrow \phi\right)}\right)}\right.$, where $\phi$ is the formula whose Gödel number is $n$.

Suppose that $\mathfrak{N}_{i-1} \vDash \operatorname{Pr}_{\mathrm{PA}}\left(\overline{\left\ulcorner\left(\theta_{n} \rightarrow \phi\right)\right\urcorner}\right)$. Then $\mathfrak{N}_{i-1} \vDash \operatorname{Pr}_{\mathrm{PA}}\left(\overline{\left\ulcorner\operatorname{Pr}_{\mathrm{PA}}\left(\overline{\left\ulcorner\left(\theta_{n} \rightarrow \phi\right)\right.}\right)\right.}\right)$.

Hence if $m=\left\ulcorner\operatorname{Pr}_{\mathrm{PA}}\left(\overline{\left\ulcorner\left(\theta_{n} \rightarrow \phi\right)\right.}\right)\right\urcorner$, then $\left.\mathfrak{N}_{i-1} \vDash \operatorname{Pr}_{\mathrm{PA}}\left(\overline{\left\ulcorner\left(\theta_{m} \rightarrow \operatorname{Pr}_{\mathrm{PA}}\left(\overline{\left\ulcorner\left(\theta_{n} \rightarrow \phi\right)\right.}\right)\right)\right.}\right\urcorner\right)$, so that $\left.\left.\mathfrak{N}_{i-1} \vDash \mathfrak{H}_{\mathrm{PA}}\left(\overline{\left\ulcorner\operatorname{Pr}_{\mathrm{PA}}\left(\overline{\left\ulcorner\left(\theta_{n} \rightarrow \phi\right)\right.}\right)\right.}\right)\right\urcorner\right)=1$, so that $\mathfrak{N}_{i} \vDash \operatorname{Pr}_{\mathrm{PA}}\left(\overline{\left\ulcorner\left(\theta_{n} \rightarrow \phi\right)\right.}\right)$, giving a contradiction.

So it must be the case that $\mathfrak{N}_{i-1} \vDash \neg \operatorname{Pr}_{\mathrm{PA}}\left(\overline{\left\ulcorner\left(\theta_{n} \rightarrow \phi\right)\right.}\right)$ while $\mathfrak{N}_{i} \vDash \operatorname{Pr}_{\mathrm{PA}}\left(\overline{\left\ulcorner\left(\theta_{n} \rightarrow \phi\right)\right.}\right)$, so that $f_{i}(n)=0$ and $f_{i+1}(n)=1$.

We also note two other facts. Firstly, we must have $n \leq k$, since $f_{i}(k) \neq f_{i+1}(k)$. Also, we must have that for all $j \geq i, f_{j}(n)=1$.

So, $1<i<j$ implies that $f_{i}<f_{j}$. Moreover, there exists $n \leq k$ such that $f_{i}(n)=0$ and $f_{j}(n)=1$. So the functions $f_{i} \backslash\{n: n \leq k\}$ are all different, for $i>1$, so there are only finitely many of them.

[^0]:    * Anything in the footnotes is not on the syllabus.
