## Some inspirational quotations

Herman Weyl: "In these days the angel of topology and the devil of abstract algebra fight for the soul of each individual mathematical domain."

Guillermo Moreno: "Groups, as men, will be known by their actions."

### Resources

- Lecture notes.
- Problem Sheet 0 and Solutions.
- Four other Problem sheets.
- Hand-out Notes with material from previous years.
- Books: J.P. Serre Trees
  - D. Kapovich: Geometric Group Theory (Chapters 7,8,11).

We will be studying countable infinite groups. Unless otherwise stated, all groups will be finitely generated.

We have two types of infinite groups:

- "Small": Infinite abelian ⊂ Nilpotent ⊂ Polycyclic ⊂ Solvable (studied in MT, C2.4 Infinite Groups).
- "Large": Free groups ⊂ Hyperbolic groups; Free groups ⊂ Amalgamated products.

### Methods used

(1) Geometric Approach: Make the group G act on an interesting metric space X. Deduce algebraic properties of G from

- the geometry of *X*
- the properties of the action of G on X

For example, X might be a Hilbert space (in particular  $\mathbb{R}^n$ ) or a differentiable/Riemannian manifold. In this course, we consider the case when X is a simplicial tree and, later, when  $X = \mathbb{H}^2_{\mathbb{R}}$  or  $X = \mathbb{H}^n_{\mathbb{R}}$ . (2) Algorithmic Approach: Design algorithms and construct Turing machines to solve algebraic questions. This works for groups described by finite data (i.e. finitely presented groups). Dehn (1912) formulated 3 fundamental problems:

- I Word Problem
- II Conjugacy Problem
- III Isomorphism Problem

Dehn solved the three problems for G acting on  $\mathbb{H}^2$  by isometries,  $G \leq \operatorname{Isom}(\mathbb{H}^2)$  discrete and  $\mathbb{H}^2/G$  compact.

However, the problems are unsolvable in general (Novikov–Boone). The example of a group with unsolvable word problem that Novikov–Boone constructed acts on a tree.

- (3) Approximation by finite groups: The idea is to take finite quotients  $G/N_k, k \in \mathbb{N}$  that become larger and larger. Ideally  $\bigcap_{k \in \mathbb{N}} N_k = \{1\}$ .
  - Residually finite groups.

### Methods used

(4) Understanding of subgroups:

- What kind of subgroups?
- Can we decompose every group G into simpler "building blocks"?
- "Small" groups: basic building blocks are abelian; the general groups obtained by iterating semidirect products, more generally short exact sequences;
- "Large" groups: we iterate amalgamated products and HNN extensions; building blocks are one-ended groups etc.;

The main trick of GGT is to move between:

Discrete world :

Graphs

Toolkit: Combinatorics, discrete maths

#### Continuous world:

 Differentiable manifolds ⊇ Riemannian manifolds
 Toolkit: Calculus

Dehn used the geometry of a continuous space (the real hyperbolic plane) to solve a problem about a discrete group. This can be done backwards: use a group/discrete structure to solve a problem about a continuous space.

### Generating sets

Given  $S \subset G$  and  $H \leq G$ , TFAE

• *H* is the smallest subgroup of *G* containing *S*;

• 
$$H = \bigcap_{S \subset K \le G} K$$
;  
•  $H = \{ s_1^{\pm 1} s_2^{\pm 1} \dots s_n^{\pm 1} \mid n \in \mathbb{N}, s_i \in S \} \cup \{ \text{id} \}.$ 

*H* is called the subgroup generated by *S*. We write  $H = \langle S \rangle$ .

- If H = G then S is called a generating set.
- If S finite then G is called finitely generated.
- If  $S = \{x\}$  then  $\langle x \rangle$  is the cyclic subgroup generated by x.
- Rank of G = minimal number of generators.

- What is "the largest infinite group" generated by *n* elements? Finite sets: A larger than  $B \Leftrightarrow card(A) \ge card(B) \Leftrightarrow$  there exists  $f : A \rightarrow B$  onto.
- Infinite groups: We look for a group  $G = \langle X \rangle$ , card(X) = n, such that for every group  $H = \langle Y \rangle$ , card(Y) = n, a bijection  $X \to Y$  extends to an onto group homomorphism.

Clearly cannot be done for any group G, e.g. if G is abelian then H would have to be abelian.

So G must be a group with no prescribed relation ("free").

 $X \neq \emptyset$ . Its elements = letters/symbols.

Take inverse letters/symbols  $X^{-1} = \{a^{-1} \mid a \in X\}$ . We call  $\mathcal{A} = X \sqcup X^{-1}$  an alphabet.

A word w in  $\mathcal{A}$  is a finite (possibly empty) string of letters in  $\mathcal{A}$ 

$$a_{i_1}^{\epsilon_1}a_{i_2}^{\epsilon_2}\cdots a_{i_k}^{\epsilon_k},$$

where  $a_i \in X, \epsilon_i = \pm 1$ .

The length of w is k.

We use the notation 1 for the empty word (the word with no letters). We say it has length 0.

A word w is reduced if it contains no pair of consecutive letters of the form  $aa^{-1}$  or  $a^{-1}a$ .

A reduction of a word w is the deletion of a pair of consecutive letters of the form  $aa^{-1}$  or  $a^{-1}a$ .

An insertion is the opposite operation: insert a pair of consecutive letters of the form  $aa^{-1}$  or  $a^{-1}a$ .

Denote by  $X^*$  the set of words in the alphabet  $\mathcal{A} = X \sqcup X^{-1}$ , empty word included.

Denote by F(X) the set of reduced words in A, empty word included.

We define an equivalence relation on  $X^*$  by  $w \sim w'$  if w' can be obtained from w by a finite sequence of reductions and insertions.

#### Proposition

 $\forall w \in X^*$ , there exists a unique  $u \in F(X)$  such that  $w \sim u$ .

#### Proof

Existence: By induction on the length.

$$w = a_1 a_2 \dots a_{n+1} \sim a_1 b_1 \dots b_k$$
 if  $a_1 b_1 \neq x x^{-1}, x^{-1} x$   
 $\sim b_2 \dots b_k$  otherwise

Uniqueness: We prove that if  $u, v \in F(X)$ ,  $u \neq v$ , then we cannot have  $u \sim v$ .

Argue by contradiction and assume we can. So there exists a sequence of reductions and insertions

$$w_0 = u \sim w_1 \sim w_2 \sim \dots \sim w_{n-1} \sim w_n = v$$

Take a sequence with  $\sum |w_i|$  minimal. As u and v are reduced,  $w_0 \to w_1$  is an insertion and  $w_{n-1} \to w_n$  is a reduction. Hence  $|w_0| < |w_1|$  and  $|w_{n-1}| > |w_n|$ . So there exists some i such that  $|w_{i-1}| < |w_i| > |w_{i+1}|$ . Say,

$$w_{i-1} \to w_i$$
 is an insertion of  $aa^{-1}$ ,  $a \in \mathcal{A}$   
 $w_i \to w_{i+1}$  is a deletion of  $bb^{-1}$ ,  $b \in \mathcal{A}$ 

Cornelia Druțu (University of Oxford)

Geometric Group Theory

$$w_{i-1} \to w_i$$
 is an insertion of  $aa^{-1}$ ,  $a \in \mathcal{A}$   
 $w_i \to w_{i+1}$  is a deletion of  $bb^{-1}$ ,  $b \in \mathcal{A}$ 

- If  $aa^{-1}$  and  $bb^{-1}$  are the same letters in  $w_i$ , then we can suppress  $w_i$  and take  $w_{i-1} = w_{i+1}$ .

- If  $aa^{-1}$  and  $bb^{-1}$  are disjoint in  $w_i$  then we change the order: first delete  $bb^{-1}$ , then insert  $aa^{-1}$ .

- If  $aa^{-1}$  and  $bb^{-1}$  have one letter in common in  $w_i$ , for example:

$$w_{i-1} = [...xyz...]$$
  
 $w_i = [...xaa^{-1}yz...]$ ,  $y = a$   
 $w_{i+1} = [...xaz...]$ 

then we can take  $w_{i-1} = w_{i+1}$ . All three are decreasing  $\sum |w_i|$ , a contradiction.

Cornelia Druțu (University of Oxford)

Geometric Group Theory

#### Definition

The free group over X is the set F(X) endowed with the product \* defined by: w \* w' is the unique reduced word equivalent to the word ww'. The unit is the empty word.

#### Example

$$\bullet \ \ \, {\rm If}\ \#X=1\ {\rm then}\ F(X)\simeq \mathbb{Z}.$$

**2** IF 
$$\#X \ge 2$$
 then  $F(X)$  not abelian.

Terminology: We say that a free non-abelian group is a group F(X) with  $card(X) \ge 2$ .

### Examples of free groups in real life: the ping-pong lemma

#### Example

Take  $r \in \mathbb{R}$ ,  $r \geq 2$ ,

$$g_1=\left(egin{array}{cc} 1 & r \\ 0 & 1 \end{array}
ight)$$
 and  $g_2=\left(egin{array}{cc} 1 & 0 \\ r & 1 \end{array}
ight).$ 

 $SL(2,\mathbb{R})$  acts by isometries on  $\mathbb{H}^2=\{z\in\mathbb{C}:\mathit{Im}(z)>0\},$  via

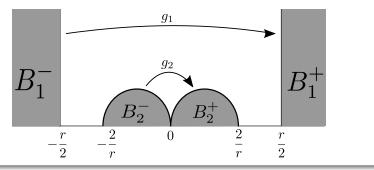

$$g \cdot z = rac{az+b}{cz+d}, \qquad g = \left(egin{array}{cc} a & b \\ c & d \end{array}
ight) \in SL(2,\mathbb{R}).$$

Statement: We have that  $\langle g_1, g_2 \rangle \leq SL(2, \mathbb{R})$  is isomorphic to  $F(\{g_1, g_2\})$ .

# Why $\langle g_1, g_2 \rangle$ is free

Statement: We have that  $\langle g_1, g_2 \rangle \leq SL(2, \mathbb{R})$  is isomorphic to  $F(\{g_1, g_2\})$ Proof

$$g_1(z) = z + r, \ g_2(z) = \frac{z}{rz+1}.$$
  
$$I(z) = -\frac{1}{z} = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} z, \ g_2 = I \circ g_1^{-1} \circ I^{-1}.$$
